> I remember a long time ago a discussion about malloc, and bugs in it. Was
> there ever a new version of malloc posted or a good fix?

The problem is in Malloc(), GEMDOS function 0x48. There is a limit on how many times you can call it, and I think you have to free memory in the reverse order. TOS 1.4 may have fixed some of these problems, but you can hardly depend on TOS 1.4 being installed in the average ST when Atari is still shipping computers without it.

Most C compilers get around the difficulties by calling Malloc() to allocate a large chunk of memory, then parceling out little chunks as necessary. You can see how this works by examining the source code to the dLibs C library.

(There is a bug in dLibs realloc() function. First person to *post* a fix gets a banana split at the Cup 'N' Cone in White Bear Lake. Transportation not included. Offer void where prohibited by cholesterol levels.)

>even better. Any langauge but Assembly, C or BASIC prefered.

Very easy. Use the ROM3 and ROM4 lines (pins 31 and 33) as strobes to enable 16 bits in parallel onto the 16 data lines. NOTE THAT THE DATA LINES ARE NOT INTERNALLY BUFFERED! If you put data on them at any time except when ROM3 or ROM4 pull low, you will cause a big fat crash!

Try this. It grabs 16 bytes in succession, then waits for data bit 8 to go high. When it does, the program knows that data are (grammar!) again available and grabs another 16. A pulse on the ROM3 line alerts the sending end of the system that a byte was grabbed, so it presents the next one. After 16 bytes, both parties should go back to the "inactive" state, with the ST checking bit 8 to ensure that the cycle has ended, and another one begun. ROM4 is only used to check for availability of the next data group. This setup was used for testing a microprocessor-controlled tablet counting machine, grabbing 16 bytes every 2 milliseconds. (Note: I may have inverted ROM3 and ROM4--but you should get the idea. Use a scope to figure them out.)

```
......
carta = (int *)0xFA0000; /* Rom3 */
cartb = (int *)0xFB0000; /* Rom4 */
unsigned char *mem;

mem = (unsigned char *)lmalloc(mem_size);

for (mem_ptr = 0; mem_ptr < mem_size; mem_ptr += 16)
{ do {raw = *cartb;} while (raw & 256); /* Wait for low */
while (!(raw & 256)) /* Wait for high */
raw = *cartb; /* Previous cycle must end */

for (i = 0; i < 16; i++)
*(mem + mem_ptr + i) = (unsigned char)*carta;
}
......
```

Hope this helps!

That won't work under old TOS (pre-1.4) because the Desktop upcases
args, making -o into -O.

Simply "jas myfile.s" should work from the Desktop -- but it doesn't. I
don't know why not, even after looking at the sources. The
argument-parsing routine is setting an error flag for some unknown reason.

It seems a very good idea to me to post them in this
newsgroup, or make them available for anonymous ftp.
(I hope there is a multitasking shell with it)
Maybe comp.sources.atari.st is a better place for posting.

From: PMR2@psuvm.psu.edu
Message-ID: <90202.200226PMR2@psuvm.psu.edu>
Source record: 50447

I have a Panasonic 3.5" DS internal drive for the IBM PC, with mounting bracket and drive-to-FDC cable but no power supply, FDC, or drive cable. I would like to use the drive with my 1Mb 520ST. (a) What parts (names, distributors) do I need to get and (b) what modifications (eg. to the ST floppy cable) do I need to make in order to use this drive? Are there any info files in the archives (eg. terminator) that might be of assistance?

Responses _greatly_ appreciated.

Paul Ricker (PMR2@PSUVM.PSU.EDU)

8. Using standard b/w monitors with an Atari

From: uttwkt@utrcu1.UUCP
Message-ID: <301@utrcu1.UUCP>
Source record: 50450

Hallo,

I am trying to install LaTeX on my Atari 1040 ST. I have the LaTeX-files
from the mailserver in Utrecht. There are, however, still some questions
open:
1) How do I change the environmentvariables for LaTeX, such as
TEXINPUTS, TEXFONTS, etc.?
2) Where do I get a printerdriver for my Epson LQ-500 24 pins printer?

If you could answer (one of) these questions, please send me some mail.
You can send it to uttwkt@utrcu1.UUCP or to hvdberg@math.utwente.nl
Thanks!!

11. Microrx call out functions?

Newsgroup: comp.sys.atari.st.tech
Date: 1990-07-23 12:36:26 UTC
From: jg@hpldola.HP.COM
Message-ID: <1146@cnps.PHILIPS.nl>
Source record: 50451

I have gotten the shareware Microrx kernel and have been playing with it.

Everything seems to work quite well. It seems like a very powerful and complete kernel.

Last night I tried to define a 'switch' call out function to simply count the number of process switches. First I tried to simply increment a global variable in a C function, but this gave quirky and often incorrect results. After reading through the Microrx documentation, I thought the problem was that the C function was munging with the registers so I wrote an assembly program that saves the registers on the stack, increments the global variable, and restores the registers, but this seems to invariably lock up my system.

Has anyone solved this problem? Or done anything with the call-out functions in Microrx?

I am using the MWC 3.0.6 development package.

Thanks in advance
Joe Gilray

Message-ID: <1990Jul23.133653.9285@usenet.ins.cwru.edu>
Source record: 50460

I've just begun fooling around with GEM (with the invaluable help of Tim Oren's series on ST programming). After writing a short program which displayed multiple windows on the screen, I was dismayed to find that it was limited to only 7. Although I can't see me writing an application needing more than this, I was wondering whether there was some way to give the OS a little more space for windowing purposes (I have a mega 4, and I'm certain that there was more ram to spare after the seven windows were displayed).

Thanks

J P pietrzak@solarium.scl.cwru.edu

20. Supexec()/Laser C Problem Solved

22. 1 Meg upgrade on an old 520ST

I'm posting for a friend, so if the terminology isn't exaclty right,
it is because you are getting it third hand:

The 256K mem chips on the 520ST have 8pins. The 1meg chips, however,
have 10pins. My friend is looking for a cheap way to upgrade memory
by just yanking out the 256Ks and replacing with 1meg chips. What do
you do with the two extra pins...? Is this kind of an upgrade
possible...? NOTE: He did do it on a 520STfm because it had a 1040
motherboard. It cost him $35 (U.S.) and about three hours time.

NOTE: This 520 does not have the RF modulator or Built in disk drive.
That should help date the equipment...

Either
-1 Build an interface to take a PC controler card; install
a lot of weird, non-compatible, software; modify ROMS
(for autoboot).
or
-2 Buy a SCSI interface (or build...) to connect the ST to a
SCSI drive. Next buy a SCSI interface that fits onto the
PC drive. This can use compatible ST software, autoboot, etc.

If you don't have the PC hard disk yet, you might just buy a SCSI drive
to start with.. . Anyway, the first solution is quite a lot of trouble.. .

To hook up a standard IBM type ST506 drive to an Atari ST you need the
following:
1) Case and power supply, fan recommended.
2) Atari SCSI host adapter. Many companies make these including
Supra, ICD, and Berkley Microsystems. Cables are provided for
connection to ST and drive/controller.
3) SCSI-ST506 controller such as Adaptec 4000(4070 if RLL) or OMTI
cables to conect drive to controller may not be provided.
4) Cables if required.
5) And of course, your hard drive.

A small amount of basic technical knowledge is required to complete the
installation. If your not sure what you're doing, it might be wise to
ask someone's assistance before attempting the process.

Good Luck,

[]
Can a Mac SE/30 (with the kind of disk drive that can read Mac
disks) read Atari ST disks in their normal format, or do the Atari disks
have to have the same modification (MSDOS bootsector) that they need to
be readable on an IBM?

The reason I ask is that I've got zillions of Atari disks, and
I will soon have a Mac, and I'd like to know if I should start writing
MSDOS boot sectors to all my disks :-) [before the Atari breaks completely.]

Thanks in advance.

28. STe memory

Newsgroup: comp.sys.atari.st.tech
Date: 1990-07-25 08:40:19 UTC
From: srs@oasis.icl.stc.co.uk
Message-ID: <543@ozz.oasis.icl.stc.co.uk>
Source record: 50472
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

Hi There,

Thanks for the response about having 2.5meg of memory in an STe. The conclusion was that if you boot with 'simmfix', then it would all be available for use with no problems. If you boot without simmfix, the machine will think you have 4meg available (assuming you put the two 1meg chips in the first two slots). Obiously this could be a problem if it tries to access the 1.5meg at the top that doesn't exist. So now I have a new question for you - can anyone tell me how the STe uses the memory it's got - if I got this system, I would be using simmfix on all my 'serious' disks, but things which autoboot (games :-) wouldn't have it. Is this likely to cause a problem?

Please reply be email, I'll summarise to the net.

Thanks

Steve

I had the same problem when I abandoned my 1040ST for a Mac SE. If you're buying your SE/30 new, it will probably come with the new high density (FDHD) drive in it. Apple provides with the drive a utility program (I think it's called Apple File Transfer) that will allow you to transfer files between the Mac and MSDOS machines.

I couldn't get the program to recognize a straight ST disk, but if I first formatted the disk as an MSDOS disk (using the Mac), I found that both machines could read from and write to it. Writing an MSDOS boot sector to an existing ST disk will probably work also.

Could someone post or e-mail the number of Berkley Microsystems? I recently read in the Spectre GCR documentation that they had a chip-fix for the two drive "ghosting" problem experienced with standard Atari hard drives. I think this is a problem which has been plaguing me for years now, and I like to get it resolved. Thanks!

A Mac SE/30 can't read ST or IBM disks. It is possible, though, to read
either on a Mac using special software (sorry, I don't remember the name;
ask on the Mac group) and a high-density mac disk drive. I'm not sure
whether the boot sector matters.

The "switch" call-out occurs at a very critical time, when no process
is actually running. The routine must be very carefully constructed.
Perhaps your routine overflowed the stack. The routines must be short
and sweet. Rather than use the stack, try to save the regs. in a
fixed area of memory. Perhaps even use your own stack area if you
expect to nest deeply into C code (not really recommended for the
switch function). If all you want to do is bump a global, how about:

```
switch:
add.l #1,_counter
rts
```

I don't see why you need to save regs or call a C routine at all.

33. RTX programming questions

Newsgroup: comp.sys.atari.st.tech
Date: 1990-07-25 17:42:55 UTC
From: jg@hpldola.HP.COM
Message-ID: <16960002@hpldola.HP.COM>
Source record: 50478

I have been using Micrortx to write a game based loosely on C-Robots.
But more about that when I'm ready to post it.

Right now I have two more Micrortx related questions:

1) I have a function that I am using as a process. I want to be able
to call this function many times and have each of the separate processes
created in this way to be able to commit suicide when they are done.
I have tried the following:

A) p_delete((char *) NULL);
B) p_delete(p_info((char *) NULL, &state));

These should work and do sometimes but other times cause an error with
the message (something like):

"Unrecoverable loop error in exception processing"

Other times the system hangs.

BTW, making the process's stack larger seems to delay the problem.
I.e. I can create more processes and have more of them successfully
commit suicide before the problem occurs.

The documentation indicates that a process should be able to commit
suicide.

The process function that is commiting suicide has four integer arguments
passed to it, could this be causing the problem? Do I need to clear
them off the stack?

2) How big should I make a process's stack (the last argument to p_create)?

I can think of two factors that affect stack size:

A) number of arguments passed to the process
B) The depth of calls made by the process.

Any ideas?

Thanks in advance
-Joe Gilray

34. Mac Emulators

Hello, I have a friend who is considering buying a Mac Emulator
for his Atari-ST. Can anyone recommend such a package and maybe
discuss limitations of such a system.

The ideal setup would also have to write disks in a Mac-readable
format, and run Mac MS-word.

Are we in dreamland or is this possible.

Any help would be truly appreciated.

thanks -- alann

I believe the same OS limitations that only allow 6 desktop accessories
keeps you from opening more than 7 windows. The OS can only address 8
different processes at once,so there's "no need" to be able to address
more windows. With 6 desk accessories, one program and the desktop,
you're out of room.

If you have the high density Mac drive, you can get a program called Dayna Dos Mounter, which will allow you to mount any MS-DOS disk right onto the desktop, and you can use it just like a Mac disk. But it does require a boot sector. (If you stick a regular Atari disk in the drive, you get the infamous, "This disk is unreadable, do you want to initialize it?")

To read a MS-DOS/ST type disk on a Mac you need the following things:

1) A Mac with a high density drive (FDHD)
2) Apple File Exchange(AFE) Utility (comes with system software 6.0+)
3) The disk must be formatted on the Mac using the AFE routine.
You can then take the disk to a ST or IBM copy files to it and get the files onto the MAC via AFE. Kind of a pain. Plus the disk performance is poor because the AFE is a standard in sequence formatter(i.e. it does not skew the sector numbers to achieve higher seek/transfer rates)

Currently, the disks must be formatted on the MAC because the AFE formats the disk slightly differently(3 sector FAT tables, hidden desktop files etc.). The AFE requires these to be before it will recognize the disk. You cannot simply write an MS-DOS boot sector to a previously formatted disk and have it work.

Because I have a Mac IIci at work(their choice not mine, although the speed, memory, 19" color monitor, and 24 bit accelerated graphics board are very nice especially since I didn't have to pay for them) I also had the need to transport files to and from the Mac. However, I found that whenever I REALLY needed to bring something in I never seemed to have one of the AFE preformatted disks around and an ST formatted disk wouldn't work. So, I pulled the custom formatter I wrote for Diamond Back II out and made it a stand alone program that supports AFE format in addition to all the other formats. It will also format AFE disks in twisted format for faster access and Power Drive 1.44 meg floopy support has been added.

I was originally just going to include it as an extra freebee with Diamond Back II. However, because it addresses several specific needs in the ST community, I have deceided to release it to a wider audiance. I will be posting it to Genie and the binaries as soon as the testing of the 1.44/1.6 meg high density Power Drive is complete. When it appears you will be able to format AFE compatible disks on your ST.

38. Emulator / Other operating system questions

Newsgroup: comp.sys.atari.st.tech
Date: 1990-07-25 23:32:51 UTC
From: n8742883@unicorn.WWU.EDU
Message-ID: <1253@unicorn.WWU.EDU>
Source record: 50476

I've been reading Comp.sys.atari.st for about two months now, and
am getting a little confused with the different types of operating
systems mentioned. I know there is the Spectre seriers which emulates
a MacIntosh, with the current Spectre being Spectre GCR. I am also
aware of the various IBM emulators out on the market; I believe that
they emulate the IBM XT well, but do not support AT emulation. I have
heard of various GEM(?)/UNIX multitasking environments, and of some
UNIX environments without multitasking which exist for the Atari series

After questioning a few atari net friends and some local ones, I feel
there is a lack of knowledge on how many different "personalities" an
atari is capable of putting on. Anyone out there wanna post a listing
of what different/alternative operating systems exist for the atari? I
know that there are at least ten curious minds who would like to know...

If I've stated anything above which is incorrect, please fix it!

Thanx a bundle,
Perry Pederson n8742883@unicorn.WWU.EDU

41. Re: STe memory

Newsgroup: comp.sys.atari.st.tech
Date: 1990-07-26 13:56:13 UTC
From: srs@oasis.icl.stc.co.uk
Message-ID: <546@ozz.oasis.icl.stc.co.uk>
Source record: 50480
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

Hi There,

Thanks again for the response about the memory in an STe. The conclusion reached was that if you had 2.5meg with the 2 1meg chips in the high priority slots, then you could boot with simmfix to get a 2.5meg machine. If you booted without simmfix, the STe would think there was 4meg available. This would cause big problems because the video memory is always allocated from the high end of RAM. I was thinking about this last night and came up with a possible solution: If you had the 2 1/4meg chips in the high priority slots and booted without simmfix, then the STe would think there was 1meg available, which is ample for all the autobooting software I can think of. Booting with simmfix would still give 2.5meg. What I would like to know is, would this method work? I can see two possible problems:

1. The STe would be trying to access the two 1meg chips thinking that they were 1/4meg chips - what would happen?

2. Does it matter what order the chips are in for simmfix to work?

Any response on this would be much appreciated, preferably by mail since the news is very slow getting here. Could some kind soul also mail me a copy of simmfix, since it doesn't appear to be at terminator. Oh, sorry, its called something else now isn't it. Shame, I thought Terminator was quite cute :-)

Thanks alot

Steve

I guess the ST hardware is too versatile for its own good, eh? Just
like EMACS... ["Extensability and Modifiability Aggravate Confirmed
Simpletons" }-)]

>a MacIntosh, with the current Spectre being Spectre GCR. I am also
>aware of the various IBM emulators out on the market; I believe that
>they emulate the IBM XT well, but do not support AT emulation. I have
>heard of various GEM(?)/UNIX multitasking environments, and of some
>UNIX environments without multitasking which exist for the Atari series

Ok, lessee what we can come up with...

In the beginning, there was... (oh, never mind.)

Magic Sac, Magic Sac+ - original & upgraded original Mac emulator, using
64K ROMs plugged into Atari cartridge port. By Dave Small.

Spectre, Spectre GCR - Mac emulator capable of using 128K Mac ROMs. GCR
can read/write native mode Mac disks, quickly. Non-GCR, MagicSac needed
the Translator One, which was very slow. (MIDI speed.)

Out in the grey->black area, we had:

Aladdin - disk based. Used 64K Mac ROM on disk? Oh well, I never saw it
working...

That pretty much covers it for Mac emulation. (I suppose the Discovery
cart from Happy Computers could go in there too, but again, grey-black.)

For PCs, first there was PC-Ditto 1, all software. Emulated an 8086 based
IBM XT, at around 1/3rd XT speed. Cool, highly compatible, but slow.

Next we have PC-Speed, imported to US by Michtron, I forgot who makes it.

Next comes PC-Ditto II. Both of these require soldering an adapter board
into your ST, like, onto the CPU or somesuch. Both index at about 4 times
faster than an IBM XT. Again, only 8086 based.

Talon Technologies brings in Supercharger, an XT-on-a-card that plugs into
the ST DMA port. Cool, fast. I've never used any of these PC emulators.

Coming soon, rumored, etc. AT-ONCE and AT-Speed, for AT emulation. Hardware,
of course.

In other, more obscure corners... CP/M-80, Apple II, Atari 8bit emulation, software based.

I think that covers the really alien emulation schemes...

What next... TOS enhancers. I'd guess MX2 and Micro-RTX are the only ones here. I've used 'em both. MX2 is free, Micro-RTX is shareware. I think Micro-RTX is far better than MX2. Both of them aim at giving you multiuser and multitasking capabilities but remaining TOS compatible. Micro-RTX is more comprehensive, and a lot more stable. MX2 comes with complete kernel source in Modula-2. (I don't know modula 2, so this doesn't help me. sigh...) Micro-RTX is very well supported by the author, Dave Beckemeyer.

A detailed comparison probably doesn't belong in this article...

Hm. MIDI-tasking, available, but only for use by MIDI software makers. Oh well.

TOS replacements? Hm. Minix, IDRIS, OS9-68000, that's all I can remember at the moment.

Minix - $100 or so, clone of version 7 unix. Small, kind of a limited system. Meant as an educational tool, not as a production, working environment. Who knows what the next version will be capable of, tho, as it's aiming for POSIX compliance.

IDRIS - don't know much about it. Unix clone, comes with X windowing system.

OS9 - don't know much about it. Source code compatible with Unix. I hear a lot of wonderful things about it, but haven't sat down to take a look yet. It ain't Unix, but it's better. (? That approach didn't work for Apollo...)

Oh, non-multitasking Unix equivalents. Gulam, Mark Williams microshell, Beckemeyer's Micro-C shell, probably several others.

Gulam is free, and probably the best command line environment you'll find, anywhere. All it needs now is integration with Micro-RTX and it'll be perfect. }-)

Mark Williams msh is kind of a hybrid of a Bourne and C shell. It comes with their C compiler system. It was OK, but I gave it up when I discovered Gulam. It's missing a lot of the C-shell features that I depend on. Gulam is a bit more thorough in its C shell features, though it's got some problems too. (Can't quote metacharacters. Very painful at times...)

Beckemeyer's Micro-C shell is a pretty thorough C shell implementation, with some nice expansions (e.g., input line editor). It's about halfway between msh and Gulam in terms of user interface power. (msh is purely a primitive command line system, Gulam is emacs-based full-screen.) I don't know how much it costs by itself, I bought the multitasking RTX-based version.

Sorry for the rambling, but I think that touches most of the points asked about.

I've been reading a lot about OS-9, and I would like to know more about it, so if anyone has information lying around about it, I would sure appreciate receiving a copy!!

Thanks,

44. atari st 3 MB memory

Newsgroup: comp.sys.atari.st.tech
Date: 1990-07-27 11:43:05 UTC
From: piet@cs.ruu.nl
Message-ID: <3652@ruuinf.cs.ruu.nl>
Source record: 50484

Please note that I am not the author of the following article. The author had some problems posting, so I did it for him. Replies should be made to:

jeroen@phil.ruu.nl (Jeroen Scheerder)

Due to manifold requests (since my original posting was badly formatted - I usually post things from xrn, which apparently has a weird editor) this articlei is reposted in an edited version.

My ST *DEFINITIVELY* has 3.0 Mb. I agree, not long ago I thought this impossible too; however, in the magazine "ST Computer" 3/1990 (a German magazine), the author K. D. Litteck describes how it is done in an article called "Aus zweieinhalb mach drei" (an error correction appeared in ST Computer 4/1990). This magazine is published in Germany by Heim Fachverlag. It is in German, and my German is not too good, but I'll try to describe the article accurately.

How does it work? Well after determining memory configuration (see below) TOS starts clearing the amount of memory it thinks is available. Say you've got 3.0 Mb available (like I do); TOS at first thinks 2 banks of 2 Mb are available and sets out to clear 4 Mbytes. It then runs into nonexistent memory when it reaches the end of the three available megabytes. An exception of type buserror occurs, and TOS determines at which adress the error occurred. This adress is then written in the TOS variable 'phystop', thus setting the correct memory size. Now TOS boots on ...
This works in all TOS versions known to mankind.
This is part 2 of an article about ST memory upgrading (technical part).

Before getting into the gruesome details, first some general ST memory theory: ST is equipped with Dynamic RAM, and for every memory location a single transistor is used. This allows for high speed and compact chips. However, the chips need to be refreshed about every 2 millisecs, of which the MMU (among other things) takes care.
The DRAMS are accessed bitwise; therefore, the ST adressing in 16 bits, only banks of 16 chips can be used. Now the adressing signal is multiplexed (at one adress line two adresses are located, that are consecutively transferred). In DRAM these adresses are then separated. This keeps the number of pins as small as possible. The multiplexing and sending control signals is catered for by the MMU too.

Now the multiplexing is the reason the DRAMS can only be increased in 4-folds; only 16 kBit, 64 kBit, 256 kBit, 1 MBit and 4 MBit chips currently exist.

Two control lines (called RAS and CAS) are of interest (both low-active). RAS transfers the low adress of the multiplexed adress line, CAS the high adress. They work too as chip-selectors. The signal WE selects READ or WRITE mode.

Furthermore, the ST divides CAS into CASL and CASH. CASL connects to the chips on adress lines 0..7 and CASH to 8..15, so that memory can be byte-accessed too. On WORD-read or write both CASL and CASH are active.

The ST's MMU can manage two banks of memory. For bank 0 the control lines RAS0, CAS0L and CAS0H are used, bank 1 uses RAS1, CAS1L and CAS1H. These banks can be equipped with 64, 256 or 1024 kBit chips.
On coldstart TOS writes patterns in memory and reads them back (all at well-chosen locations) to determine the memory configuration, and stores in the system variable memconf (adress $424) and the MMU's configuration register ($FF8001) a configuration byte:

Bank 0: Bank 1: Value: Total memory:

512 k - $04 0.5 M
512 k 512 k $05 1.0 M
2.0 M - $08 2.0 M
2.0 M 512 k $09 2.5 M
512 k 2.0 M $06 2.5 M
2.0 M 2.0 M $0A 4.0 M

(I hope this is right - anyway, it's in all good ST literature)

On top of all this, MMU also manages to make memory contiguous: allthough the adress space of each bank is 2.0 Mb, in case your bank 0 is 512 k and 1 is 2.0 M the MMU concatenates the total adressing space to a contiguous one (as TOS expects).

Now, that's all very well: now we want to fool the MMU to handle up to 5 (!) memory banks.

A scan of the electronics schematic in MacPaint format (you need it!) is posted too (binhexed and stuffed with Stuffit). This schematic is corrected for the error in the original printing.

We need adress line A9 (not used on 256 kBit chips). It is multiplexed and contains the real adresses A18 and A19. Both NAND-gates serve as OR-gate and should release the D-Latch 1 and 2 when CAS1L or CAS1H become active. An IC 74LS375 demultiplexes and gets out of A9 the adresses A18 and A19. With the D-Latch 3 A18 is obtained, with D-Latch 1 A19. A18 is also led over D-latch 2, being kept until CAS goes high. The IC 74LS139 (2-bit binary decoder) produces with A18, A19, CAS1L and CAS1H eight new CAS signals, of which we only need four. These four signals are fed to the memory banks (all formerly 0).

Now, some things to pay attention to:
- the 2.0 Mb should be bank 0;
- the RAS0-line must be interrupted;
- the assignment of RAS- and CAS-lines MUST be corresponding.

MMU pin configuration:
6: CAS0H
7: CAS0L

8: RAS0
18: RAS1
21: CAS1L
22: CAS1H
64: A9

Components:
- 1 IC 74LS00
- 1 IC 74LS375
- 1 IC 74LS139
- 4 68 Ohm resistors
- 1 Block condensator
- 1 microFahrad wire or copper litze

I hope this is clear enough to you all (once you've seen the picture accompanying this, I hope).

Wish y'all good luck,

Jeroen.

Howard - I had a real Aladin on loan once - the commercial product was a ROM-based system. I have seen disk-based systems (presumably pirates) which appear to stem from the same source; did not one of the authors posted some material on this subject a few months back?

I just got my first hard drive (yaaay) and an ICD adapter to run it. The ICD software lets you set how many folder buffers to be active. (to avoid the infamous 40-folder limit bug). What is a good,safe amount to use?

Thanks,
Brian Daniels

47. Extending your cartridge port

Newsgroup: comp.sys.atari.st.tech
Date: 1990-07-28 20:13:13 UTC
From: brian@wolves.uucp
Message-ID: <1990Jul28.201313.21802@wolves.uucp>
Source record: 50487

I am putting my motherboard into a new case this week, and was wondering if you can safely use ribbon cable to extend the ST's cartridge port. Also, could you get away with making an extension cable that had more than one cartridge connector on it, with a switch to choose which one to power?

Thanks in advance,
Brian Daniels

48. TOS or GEM ??

Newsgroup: comp.sys.atari.st.tech
Date: 1990-07-30 09:08:07 UTC
From: stefan@hpbbi4BBN.HP.COM
Message-ID: <7120001@hpbbi4BBN.HP.COM>
Source record: 50488

Does anyone how a program can detect if it was started

as a
GEM-Application
or as a
TOS-Program

I want to check if a program accidently was started
by an TOS-Shell.

Thanks Stefan

49. Right Mouse Button Programming

Newsgroup: comp.sys.atari.st.tech
Date: 1990-07-30 13:29:13 UTC
From: mreiss@ncrcam.Cambridge.NCR.COM
Message-ID: <1961@ncrcam.Cambridge.NCR.COM>
Source record: 50489

We are currently working on a project that we need to use the right mouse button. (Really both buttons, but ...) We have been able to get the left button to work fine ... single clicks, double clicks, event time out ... using evnt_multi. It will not work for the right button. The programming is the same, but it won't work. WHY ?

I really need some help here. PLEASE ... don't assume someone else will answer. If you know what the problem is please send me email.

What? You want to know what we are doing? Well.... I won't tell and I won't answer email with questions about it until its done, but can you say mg with mouse support? WE have the left button working, but we want the right button to work also. PLEASE HELP

From article <1961@ncrcam.Cambridge.NCR.COM>, by mreiss@ncrcam.Cambridge.NCR.COM (mreiss):
>
> We are currently working on a project that we need to use the right mouse
> button. (Really both buttons, but ...) We have been able to get the left

> Michael A. Reiss |
> | mike
> USENET = Mike.Reiss@Cambridge.NCR.COM |

We was doing a project that required the use of both buttons a few months ago, and people suggested we stray from the easy event multi approach and write our own mouse handlers... Didn't know much about that approach, but once you got one working I am sure it would be much better than the double button support of event multi.

As I recall you can have event multi report on left button, right button, both buttons (pressed at the same time), or neither buttons. You can't have it respond to a left click OR a right click (Which is quite a shame). Our solution was to set it to respond to NEITHER buttons, which after still requesting mouse button events, made it fall out no matter what happened. We did some experimenting and found out how to make it work.

With the event multi CONSTANTLY falling through, we could check that the variables of the event multi that had to do with the button states. Thus we could tell what was happening to EITHER/BOTH of the mouse buttons. We may have used the event mouse for certain loops, but the concept is the same.

This approach seems to actually be defeating the purpose of the event multi, which drops out on a specified event. In our case we ended up using it as a mouse button status reader, and if no buttons were pressed our code, after doing nothing, eventually looped back to the event multi to continue again.

51. 1.44M 3.5 disks // floppies as swap space

Newsgroup: comp.sys.atari.st.tech
Date: 1990-07-31 16:56:03 UTC
From: schultzd@kira.uucp
Message-ID: <1990Jul31.165603.20869@msuinfo.cl.msu.edu>
Source record: 50391

Two unrelated questions:

1.) (For a friend)... I know this has been hashed out already, so
just e-mail a reply. I need the details of how to hook up a 1.44M
drive to the ST. I remember it involved adding an extra clock line.
I also remember someone making some kind of "smart" driver to switch
between 720K and 1.44M. Can someone help me out and mail me all the
DETAILS on this?

2.) Is there any program that allows you to use a floppy drive as
swap space to get more memory in an ST. I realize this would be
painfully slow, but until I can afford more mem, it would have to do.
It would be infinitely more helpful on a nig hard drive. (Set aside
an x meg partition on the hard drive and treat it as internal memory.
Virtual mem on the ST!!!)

52. Re: Right Mouse Button Programming

Newsgroup: comp.sys.atari.st.tech
Date: 1990-07-31 18:48:07 UTC
From: saj@chinet.chi.il.us
Message-ID: <1990Jul31.184807.25820@chinet.chi.il.us>
Source record: 50392

There are 2 attractive ways to use both mouse buttons (that I know of). When Atari people have replied to such inquiries in the past, they've suggested intercepting the mouse button interrupt vector, recording what the mouse button state is, and passing control to the original mouse button handler. Your program can read the recorded state at its convenience. That method is solid and supported, but I hate having a program in supervisor mode even a microsecond longer than necessary. There is a documented extended line-A variable which tracks the state of the mouse buttons. You can poll it (possibly as part of the timer event handling of an evnt_multi() loop) and act accordingly.
Steve J.

53. Trouble hooking up second SCSI device

Newsgroup: comp.sys.atari.st.tech
Date: 1990-07-31 19:09:28 UTC
From: steve@thelake.mn.org
Message-ID: <A1898845439@thelake.mn.org>
Source record: 50393

I've been using my homebrew hard drive for a year or so with no
difficulties. Recently I bought a (used) Seagate 138N. I recabled
my system, running a 50-line ribbon from my Supra host adaptor
to the Seagate (where I tapped the line) to my Adaptec, which controls
an ancient Wren I.

The Adaptec is configured as SCSI 1 (and has been all along).
The Seagate is configured as SCSI 0.

Now comes my problem.

I can't use both drives. I can use one or the other with no difficulty.
But if both controllers are powered up, only SCSI 0 works.

Oddly enough, I can park and unpark both drives. I just can't interact
with the Wren if the Seagate is on-line. The Seagate is C-D-E; I should
be able to use the Wren as F-G-H-I if Supra's tech people are right.
But those devices do not exist, so far as TOS is concerned.

(I do have Supra's boot software installed on both drives.)

Supra tech support said I should remove the SCSI terminators from both
controllers -- but I find no terminators on either. The Seagate has 10
long pins pointing rearward next to the ribbon connector. The pins are
naked. The Adaptec has nothing at all near the ribbon connector. It has
16 naked pins next to the ST-506 control cable, but I assume they
are for connecting a second ST-506 drive.

Is there something I'm missing here? Would it help to reconfigure the
Adaptec to 0 and the Seagate to 1? (How do I do that?)

[I wanted to send this as mail, but it bounced...]

[Stefan asked how to know whether a program was started from a TOS-only
shell...]
I didn't try it, but I think this will make applinit return a failure.
On which occasions can it fail anyway (except this one)?

Hope this helps,
RIPLEY

> A) p_delete((char *) NULL);
> B) p_delete(p_info((char *) NULL, &state));
>

The first case should work. The second argument in the second case is
ignored. If it isn't working all the time, then it's likly that some
RTX data structure is getting clobered. Perhaps you are overflowing
your stack, or have a bad pointer, or overran a Malloc'ed area.

SInce the function is started with p_create, it is also legal to
simply "fall off" the end of the function or do a "return"; this
also kills the process.

>2) How big should I make a process's stack (the last argument to p_create)?
>
> I can think of two factors that affect stack size:
>
> A) number of arguments passed to the process
> B) The depth of calls made by the process.
>

Another thing to watch for is using library routines supplied by the
compiler vendor; these often use up lot's of stack space. You also have
to factor in all "automatic" variables which also require stack space.
Some RTX kernel calls also use stack space and so do some other system
calls (GEMDOS, BIOS, etc.). If you can spare it, during debugging,
allocate 2K or 4K for "normal" stacks, and perhaps 16K for "big" stacks.

To verify stack overflows, try a really big stack like 64K and see if the
problems go away.

>Virtual mem on the ST!!!)

Without a MMU this is impossible I think. Because you cannot have
contiguous memory anymore, the MMU must make it look like contiguous.

Another possibility is overlays. Then you must split larger programs in
parts that fit in the memory, and if you jump to another part, another
overlay comes in. I think the new Turbo C for the PC only has
added automatical management of overlays.

Every non AUTO folder program can call appl_init() succesfully,
The only way to find out if the program was lauched from a TOS-only shell
(I guess you mean command line shell), is to check the parent basepage
you can find the through the system variable that points to the
OS-header (can't remeber the name, and don't know the location by heart)

Tried to send this to stefan but it keeps bouncing

[Another message I wanted to mail but it bounced... :-( ]

[Q: How to use diskspace as additional memory?]
How do you want to handle page faults (or similar)? The 68000 has a bug
there and cannot continue exactly at the point the missing data got it!

With a 68010 it'd work, but then you have the different stack-allocation
at traps...

That's why TOS has to be patched to work with a 68020 (PAK-68) and some
programs won't work anymore - even some which don't do illegal things...

It should work on a TT.

Greetings,
RIPLEY

Source record: 50400

Well folks, I am going to take the plunge and buy a HD. One question comes to mind about power. Will the ICD host adaptor need a line from the power supply? Will it be the same type that goes into the drive mech? Any hints or suggestions will be welcome, I will post a summery. I plan to use a power supply for a PC case (200w), and it has 3 of the standard 4 (or maybe 5) pin trapezoidal power plugs coming out of it. Also, what software is best/required to boot my system from my HD, and to get around the 16mb partition size limit?

61. Answer to Right Mouse Button question

Newsgroup: comp.sys.atari.st.tech
Date: 1990-08-02 12:59:21 UTC
From: mreiss@ncrcam.Cambridge.NCR.COM
Message-ID: <1969@ncrcam.Cambridge.NCR.COM>
Source record: 50401

Earlier this week (or was it last week) I asked a question about using
the right mouse butoon and about using both mouse buttons. I got several
answers. Most of them were of the type - well, you can't do what you want
really, but here's a way to get around it. I want to thank all of these
people for there responses.

I got answers from Claus Pederson, Greg Lindahl, and George Reimer. Thank
you all for these answers. In lieu of anything else, we probably would
have chosen one of these solutions and done the best we could have. These
solutions would have worked, that was obvious.

However, I got another message from Jan Timm. I don't know what his source
is, but I have sent him (I believe Jan is a him, but he could be a her. If
I am making an incorrect assumption I apologize.) a letter requesting that
info. I am appending to this message Jan Timm's e-mail answer to my
request. It is obviously the "correct" answer. We have tested it and
it works !!! GREAT !!!

Again thanks to all who answered and special thanks to Jan Timm.

> USENET = Mike.Reiss@Cambridge.NCR.COM |

Hi,
I don't know what the problem is, but I read the following
should work: (with EVNT_BUTTON or EVNT_MULTI)
Set the parameters as follows:
bclicks mod 256 = #clicks ==> 2 for doubleclicking
if blicks div 256 == 1 then negate the following condition.

bmask : Bit0 set: check for left button according to bstate
Bit1 set: check for right button ...

bstate : Bit0 : 1 - left button pressed
0 - left button released
Bit1 : 1 - right button pressed
0 - right button released

==> e.g. wait for "not both released" = "left OR right pressed":
bclicks=267 (click) or 258 (doubleclick) /* NOT */
bmask=3 /* check left AND right */
bstate=0 /* left released, right released */

ev_bbutton lets you know which button was pressed then:
1 = left, 2 = right.

OK, maybe you knew all that, or maybe it doesn't work,
if it did help you, let me know.

Bye, Jan.

62. Color monitor jitters

Newsgroup: comp.sys.atari.st.tech
Date: 1990-08-02 14:01:17 UTC
From: WILSOPR@gecrdvm1.crd.ge.com
Message-ID: <90214.100117WILSOPR@GECRDVM1.BITNET>
Source record: 50402

Help!
I am, and have been having a problem with my color monitor. It appears
that the screen is vibrating horizontally, randomly with about 1 pixel
in width. This only happens in low resolution, medium is fine. It does
seem to be related to the amount of time the monitor has been on, the longer
on the more jitter.

I hope there might be an easy fix for this!

Paul Wilson

63. What should I call mg2a with additions

Newsgroup: comp.sys.atari.st.tech
Date: 1990-08-02 14:47:30 UTC
From: mreiss@ncrcam.Cambridge.NCR.COM
Message-ID: <1970@ncrcam.Cambridge.NCR.COM>
Source record: 50403

O.K. Now that our mouse stuff works, we are almost ready to make this software available. But first, is anyone else interested in it? I don't want to do all the rest of this stuff for nothing. Let me know.

What is it? Well, my son and I took mg2a (formerly Micro GNU Emacs) and added. We were tired of having to use three different editors for things so we consolidated.

We added support for Personal Pascal. In the case of Personal Pascal, this means that the compiler can call this editor with the error line and column. The editor initializes to that line and column just like the Personal Pascal editor does. But now we have an emacs style editor to use for our editing. Also we have included a "save file and exit to the Pascal compiler" function. We like it for this purpose.

We added support for Mark Williams C. Mark Williams C version of an emacs editor that we have works well. It just has some difference with mg and mg seems to be closer to GNU emacs for my taste (your mileage may vary). Besides, we have the source for mg2a. So for MWC, we added the error buffer handling. With this, we can take an error file and use it to start up an editing session of the corresponding c file and use it to move around inside the c file from one error to another. A very hany feature.

Finally we added mouse support. I know that there are emacs clones around with mouse support, but I have never found one I can use on the Atari. My son did this part. Good job, Joe. These mouse functions can be used with the Personal Pascal editor or the Mark Williams C editor, or as just a plain old vanilla ascii editor.

So that's it. We have it. Joe is using it now, and I will bring it to work and start using it in a day or two. Is anyone else interested in it? If there is enough interest I will figure out how to post it to the binaries and or sources group. If small interest, I will email it to you. If no interest then we keep it for ourselves.

Before you decide (if you are still reading my ramblings), you can answer me one question. The other alternative I see is to use full GNU emacs. I have a couple of problems with it. First it is big. Therefore it takes a chunk of hard disk space and it takes a while to load. Second, is it just me or does everyone get the carriage returns (^M) in their buffers. Is there a way to edit Atari standard ascii source (the ones with the ^M in the buffer) without having them get in the way in GNU emacs? I don't want to type them in special and I don't like seeing them on the screen. What do others do?

Well that's it. Let me know if you are interested or if you have an answer.

I have some 1 megabit RAMS that I would like to put in my ST
to upgrade but I'm not sure iff they'll work.
My question is:
Which ones do I use and will my
Hitachi HM51000-10 (100 ns) parts work ?

I hope that there is somebody out there that has done thier own
home brew megabit upgrades.
I have done a home brew 256k bit upgrade to 1 meg but would now like
to remove it and put the 1m bit chips in for 2.5 megs.

WISH: If someone has done it with 51000, can you tell how to wire
these puppies up ?

THANX in ADVANCE, Paul Moreau.

I wouldn't call it a bug. I doubt the 68000 ever had "support VM" in it's
design spec, and MC never tryed to fool anyone into thinking it did support
VM. ('tho a great many little Unix boxes used the 68000 with swaping, not
paging, and they used the XOR insn to hit the lowest point on the stack that
a function would use, as part of some kludge that the ST can't do anyway
because it's "MMU" really doesn't do any V->P mapping).

At worst it's a design oversite in the 68000. The 68010 was really the
first in the 68K line that was designed to support VM.

The SPL sound format for the Atari is another popular way of storing digitized sound. It's similar to SND except SND appends a speed byte to play the sound at the proper speed.

There is a PD program called Babel that converts Mac, Amiga, and other ST formats into SND or SPL.

From: rosenkra@convex1.convex.com
Message-ID: <104584@convex.convex.com>
Source record: 50408

---
i am writing a csh(1) because i just can't live without pipes any longer. when finished, i will post bin AND src to the net. i like gulam, but use microemacs 3.10 so gulam really buys be nothing.

anyway, i'd like to impliment the "gem" command. here are some questions i need to find out:

1) besides turning on the mouse, turning off the cursor before the command (reversing on exit), is there anything else i need to do?

2) do i have to install the shell as .prg or can it be .ttp? if it is .prg, is there any need to do vdi (i.e. can i use line A to show the mouse)? is there a better solution?

i'd like for the shell to impliment soft links and mounted file systems (!) as well, so i can use an /etc/fstab at least from the shell's point of view. i'd like to make the shell know about /etc/termcap, if possible, too. plenty of work ahead, don't expect anything before christmas, i suspect. i'll probably switch to dlibs and add support for "/" paths switched via the environment somehow. i'll probably merge my libc.a with dlibs2, if dale will let me, and post the new library as well. we'll see...

thanx for your help...

Source record: 50409

brian@wolves.uucp (Brian Daniels) writes:

>I am putting my motherboard into a new case this week, and was wondering if
>you can safely use ribbon cable to extend the ST's cartridge port. Also,

Yes, but if You get problems accessing cartridges over the cable, use
some drivers (74ALS244 for example). All lines on the cartridge port are
unidirectional, so there should be no problem.

>could you get away with making an extension cable that had more than one
>cartridge connector on it, with a switch to choose which one to power?

No.
Most cartridges will contain just EPROMs - that's what the cartridge
port is for.
Most EPROMs are rated to input voltages (adress and data lines) from 0 V
to Vcc+0.5 V.
If You switch off power for one cartridge, the EPROMs will see input
voltages of Vcc+5 Volts. Thats too much (some CMOS EPROMs will than take
the 5 Volts from the -CS line as power source and go off when
selected...)

It's probably safe to use pullups (say 100 kOhms) for the four select
lines on every cartridge, open drain drivers for the select lines and a
switch to select, which cartridge will get the select.

All STE and Hard drive Owners I recomend you use a verify function on your Hard disk driver, an expplanation and question follow. (longish)

I have resently purchased a Third Coast Drive (65 Meg ST277-1 using an ICD Advantage plus Host adapter.)

I had endless hastles with the Drive and to Third Coasts credit they spent the best part of the day with me trying to fix the problem. After changing the original ST177N (3 1/2 inch mechanism) and the Host board we concluded that the problem must be a new DMA chip. Changing the chip (actually appeared to be a standard STFM chip) did not solve the problem. Anyway in the end they exchanged the entire mother board. (Both drive and computer where purchased from TCT.) This solved the problem on initial testing. The drive partitioned and performed with no problems for about 30mins and 60meg of data shuffleing arround it.

On arriving home and using the drive to install all my software after about 3 hours the write errors started to creep back. I have narrowed the problem down to the STE as I turned the drive off overnight but left the STe powered up overnight. On reseting the system and powering up the drive write errors abound.

My question is, how can I stop this degradation of performance, I assume shortening the DMA lead may help but to what extent? The lead is currently 36inches long.

Finally I would like to say thanks again to Third Coast.

Dave Halliday.

According to Start Magazine, Frank Foster, acting in an official position as an Atari spokesperson, claimed that any multitasking system on the ST using a 68000 is a kludge, implying that Micro RTX and MT C-Shell are kludges. He also referred directly to Micro RTX and MT C-Shell by name, saying that they "[work] but not very well".

I am now seeking "expert witnesses" to dispute these claims. If you are familiar with Micro RTX and/or MT C-Shell and would like to help me with this, please contact me at (415) 530-9637.

Thank you.

First, thanks to all that replied to my earlier questions. I am still receiving answers, and will post a summary.

Is there a difference in price, performance, ease of expandability, etc, between a host adaptor/controller card/bare drive system and a host adaptor/SCSI device setup. I have a friend that has two Tandon drives hooked to an Adaptec 4000 and ICD host. He feels that the cost of the controller card is more than made up in the money saved buying non-SCSI drives. Please email answers to me, I will include them in the summary. I would also like to hear about drive/card/host combinations that work (I have heard of some pretty wierd ones). Also, a good source for new/refurbed drives would be nice!

If you are using just a plain-vanilla 68000 in your machine, this is completely impossible. If you have installed a 68010 in your ST (I tried it, and was in the process of hacking TOS to work with the '010, but lost interest), there MIGHT be a way to do it (the 68010 has some _really crude_ method built-in for handling memory swaps). If you somehow shove a 68030 into your ST's 68000 socket, you would then be able to use the '030's built-in PMMU (paged memory management unit) to do the dirty work for you (the "Virtual" INIT for the Mac does this, and I would assume something similar could be whipped up by some intrepid ST programmer.

I've been having this problem with my 520ST for years. It seems to be heat sensitive, and it is most likely in the ST itself rather than in the monitor.

I hardly ever use low-res so I don't notice it much, but the last time I saw it, I accidently noticed that it went away (for a while) by turning on and off the ST power. Can't say this will work again or not.

The ICD Advantage addapter comes with a power lead that plugs into a
power supply at one end and splits to provide power for one drive and
the host board. The standard PC power suply (200w) should be fine for
about 5 Drives. The ICD software also comes with the host adapter and
will overcome the 16MB limit. Note: if you have TOS 1.4 + the limit is
actualy 32MB.

The power supply ICD recommends needs "45 watts with 3 amps of +5 vdc and 2
amps of +12 vdc". Any IBM power supply should do, and yes you'll need to
have a +5 and a ground going to the host adaptor.

>or suggestions will be welcome, I will post a summery. I plan to use a power
>supply for a PC case (200w), and it has 3 of the standard 4 (or maybe 5) pin
>trapezoidal power plugs coming out of it. Also, what software is best/required

Well when you purchase the Host Adaptor, you should receive ICD's hard drive
utilities disk. I've never run into any problems with their handler. The
formatting utilities are great--they handle just about any controller/hard
drive configuration.

Well, to sum it up for you, here's the recipe you'll need to build an ICD kit:

1 power supply (as mentioned above)
1 host adaptor, boot disk, and installation guide from ICD
1 SCSI disk controller, an Adaptec or an Omti controller will do fine
1 Hard Drive of just about any flavor, ICD can configure to most; and if you
can't figure out the configuration for it, call ICD and they'll help you out.
1 20 pin ribbon cable
1 34 pin ribbon cable
1 50 pin ribbon cable (all with the connectors)
1 DMA cable to run between the ST and the host adaptor
optionally you can pick up a case ICD also sells that's pretty slick.

I should also mention too that the host adaptor also has a battery backed-up
clock on it. With the software I mentioned earlier your system has a nice
clock. (I used to *hate* setting the date all the time by hand.)

Welp, good luck!

I have one of the older 1040STf's (no TV output). I have recently been experiencing the following effects:

Sometimes, on bootup (or reset) the computer will act as if it cannot find the Desktop.inf file (i.e. comes up in low res, no open windows, etc). This used to happen occasionally, but seems to happen a lot more often now that I have a 20MB HD on an ICD interface. Anyone else know what's going on/have had the same problem?

Thanks in advance,
Brian Daniels

I had some trouble with this stuff too, but I've gotten it figured out now.

First, you can use any name you want for the auto load macro file; you set
the name in one of the option menus and then "save setup".
(Sorry, my ST is packed in boxes right now so I can't say exactly which menu
to look for.)

There is what I'd call a bug in the auto-dialer, (or at the very least a
misfeature!) in that it looks for macro files in the current working directory,
instead of the startup directory. Thus, if you change paths after invoking
Uniterm, your dialer macro files won't get invoked when you dial a host. I
got around this problem by setting up function keys to invoke programs. First
%copy($C,1) to save the current path into variable 1, then set the path, then
invoke an external program, then reset $C to $1. I have one function key that
saves the path, puts up a selector for the program to invoke, then invokes
the program and restores the path.

83. Shift key problem - hardware or software?

Newsgroup: comp.sys.atari.st.tech
Date: 1990-08-07 12:29:46 UTC
From: grahamt@syma.sussex.ac.uk
Message-ID: <3204@syma.sussex.ac.uk>
Source record: 50422

Can anyone give me advice on whether a problem I've found is likely to be a hardware or a software problem?

I recently upgraded my old (March 86) 520ST to TOS 1.4. In the course of fitting the ROMs I ham-fistedly dislodged my RAM upgrade board and, apparently, did something to the glue chip. My local repairman fixed it up and it now works - almost - perfectly. I should add that this ST does not have an internal disk drive or power supply, and it has a rev.C board. (I told you it was old.)

Today I noticed that the right shift key was misbehaving: it was actually sending characters. Usually it sent two at a time, mainly characters from the lowest row on the keyboard - typical combinations for each keypress were: vn /N M, /O n. Sometimes it only sent one character. I couldn't find any pattern.

I wrote a small program to print out scancodes and ascii codes for the characters. (In the course of this I found out that, using Laser C at least, the following code fragments put different values into 'keycode':

```
A. long keycode;
keycode = Cconin();
printf("\n%lx",keycode);
```

```
B. long keycode;
keycode = Bconin(2);
printf("\n%lx",keycode);
```

Sheldon Leeman's book on TOS says that both of these should return both the scancode and the ascii value of the key in 'keycode'. I found that only Bconin(2) does this, whereas Cconin() gives you just the ascii value. Anyway, this is an aside.)

In the course of running this program a couple of times, the shift key suddenly started behaving itself again! I tried several things - running the program inside and outside the Laser C shell, rebooting with warm and cold boots, etc. Once, after I'd cold booted, the problem came back, only to go away again after a few minutes. The next time I cold booted the shift key stayed OK. Oh, and I wasn't running any auto progs or accessories at the time.

Anyone got any clues?

Graham

Its under Settings on the menu bar, Terminal 2. It asks for a name for the auto-start macro.

On another note, I would love to have a copy of the Uniterm manual, but I can't get TeX to work. If anybody could send me a postscript file of it I would really appreciate it!!

You never really mentioned what problems you had with your drive? If it was constant write failures then this may be a fault which Atari has actually (tried) to fix. Well, at least there is a hardware modification suggested by Atari to get bothersome drives to work.

However, I believe Ataris instructions were somewhat confused but I'm trying to find out currently whether I can get my Power Drive fixed. (But in this case the problem is crashing upon reset).

When I got my STE it totally crashed my hard drive and writes always failed. Best Prices checked my machine with a Megafile 30 and it worked, but they sent me a new machine anyway. I've had absolutely no write problems (or read for that matter) with the new machine. Maybe you could ask your dealer(?) for a replacement.

Mark.

86. TOS 1.6 and hard drives

Newsgroup: comp.sys.atari.st.tech
Date: 1990-08-07 20:40:18 UTC
From: aimd@castle.ed.ac.uk
Message-ID: <5570@castle.ed.ac.uk>
Source record: 50426

A while ago Alan Pratt wrote an interesting letter about what the ST (STE) does when it boots up. He said that upon booting the machine waited 90 seconds for a signal from a hard drive which may be attached to the machine. This time limit could, I think he said, be cut by pressing a key.

My hard drive is one of those annoying ones which wont respond at all until it has reached speed. However, I have never been able to get it to autoboot without using a 'sleep' utility.

The problem could, of course, be that the drive simply takes longer than 90 seconds to get to speed but, to be honest, I have never noticed my STE wait that long!

When I switch on my STE the floppy light is out. The machine waits maybe 10 seconds at the most and then the floppy starts to look for a disk. After that, if there is no disk, it slow boots as my STFM did by checking the disk drive occasionally. Is that the 90 seconds Alan means?

This has been annoying me for a while. Is the UK 1.6 rom the same as the US in this respect.

Any help appreciated...

Mark.

> Adam Tilghman

Why not try the 68070 from Signetics. I have only read the data sheet
but it seems to be a nifty chip, it has a built in mmu (a little
limited in that it will only handle either 8 2Mb pages or 128 segments
of up to 128kbytes each, I may be reading this wrong but I'll need the
hardware manual to find out for sure), 2 DMA chanels, a UART, and a
I^2C interface (a syncrounos serial port). It uses a 30Mhz xtal but
cuts it in half for internal use so it runs at 16Mhz. It is in a
84-Pin PLCC package and the pins are mostly the same, a few extras to
handle the internal stuff. It is supposed to be object code compatible
with the 68000 and costs about $50 small quantity.

This could be an interesting hack, using a jato board to get upto
running at 16Mhz with out killing the ST and to supply a 68881. You
would then mount the 68070 some support electronics and the jato board
on another daughter board and voila you have a ST with unlimited
virtual memory (a lot of patching to the operating system of course so
that the machine will allow memory access above 4Mb with out an error,
or trap the error and use it? And to allow swapping). You can then add
another serial port (2 if you want to use the I^2C lines), rewrite the
file system to use one of the DMA ports (will speed up the file system
when using multitasking systems) and lots of other things I have not
even touched on. This is all assuming that you could even interface
the 68070 to the ST, should be possible but its the hidden gotchas
that hurt the most.

A point of fact, the _really crude_ method mentioned above is nothing
more than allowing the 68010 to restart an instruction after servicing
a bus exception. A 68000 will start on the next instruction and you
will lose the previous instruction witch will probably result in your
system crashing in massive flames. I rather resent Motarola for say
that it "supports Virtual Memory/Machine" when infact you still
require a MMU to do that stuff.

Anyhow this was just my thoughts on how one might realy screw up a perfectly good ST.

Hello,
I wonder if anybody out there could help me with a small problem. I want to scan the ST keyboard directly, ie obtain from it the codes for keys up and down, and (possibly) bypass the usual keyboard scanning routines. I need to do this to find out when keys are pressed simultaneously.
I noticed a bios (xbios ?) call that returned an address of a pointer table to various input routines (such as mouse, MIDI, input etc).
Is it just possible to save the keyboard vector (the last one?), plug in my own for a while, and then reset the original vector on exit? What, if any, special properties does one of these vector routines require? Will it be possible to still use a debugger (MONST2) to trace the program even when the keyboard input routine has been moved, and if not what could be done?
Any help will be appreciated, source code or explanations, either emailed directly to me, or on the net.

Thanks,
Andrew

Has anybody converted this schematic to an atari-readable format?
I would like to upgrade my 1040, but I cannot use binhex and stuff
(there is no conection between our department's Mac and the outside
world).
I emailed the author, but I got no response, so if anybody has the
schematic in some atari-usable (PI3, IMG, ...) format, could you please
mail it to me?
Thanks,

My problem was constant write fails. The problem after Third coast kindly
changed my STE is occasional write errors (only when machine is very hot.)

To partialy solve the problem I have removed the metal shielding and raided the
machine 5mm of the desk. This improved ventilation meens I can use my STE for
about 6 - 7 hours befor the first write error arrives.

>However, I believe Ataris instructions were somewhat confused but I'm
>trying to find out currently whether I can get my Power Drive fixed.

92. Yet another (different) problem with STE and HD.

Newsgroup: comp.sys.atari.st.tech
Date: 1990-08-10 18:59:41 UTC
From: D.C.Halliday@newcastle.ac.uk
Message-ID: <1990Aug10.185941.11336@newcastle.ac.uk>
Source record: 50434

Having almost solved the consistent write error fault by changing my STE. I now have another problem I hope someone out there can help with.

The problem is that when I boot the STE (leaving plenty of time for drive to run to speed) Gemdos does not recognise my flopies, sometimes (usually when not quite waiting long enough for the HD to build up speed) no icons for A or B will be seen on the desktop. The other times the icons appear but when clicked on I get the message 'Drive not known to GDOS.' The flopies respond as normal after I have reset the computer.

The setup is STE (2meg), ICD host addapter (advantage plus), segate ST277N-1 (or is it ST177N-1?) anyway its the 5 1/2 inch version.

I formatted the drive with a very resent verion of the ICD utils, but ran Bootfix just in case.

Finally I have considered one solution, write an auto folder program to check the existance of A and if it is not found then perform a reboot. But is there a better way and if not has anybody written such a prog yet?

Many Thanks,

Dave H.

97. Spurious interrupt

Newsgroup: comp.sys.atari.st.tech
Date: 1990-08-13 08:10:12 UTC
From: leo@ehviea.ine.philips.nl
Message-ID: <883@ehviea.ine.philips.nl>
Source record: 50437

For the record: I am currently developing a MIDI recorder program; most of it works already - still have to add some windowing stuff.

One part of the recorder is a metronome, that can be adjusted on the fly (that is, you can alter the beats/minute while recording/playing, which effectively can alter replay speed). The metronome is based on Timer A; the interrupt routine increments a global variable, then clears bit 5 of $ffff0a (if memory serves right). When the metronome is altered, Xbtimer() is called with new parameters that reflect the new timer A registers.

Now for the problem: this setup works - most of the time. Occasionally when I alter the metronome a lot, a spurious interrupt occurs: exception 24 (I get 24 bombs). From my MC68000 manual I believe this is more or less a fake interrupt, a hardware designer might use it to indicate that an extern exception occured (such as a bus error of the MFP68nnn). Could it be that Xbtimer() is affecting the MFP68nnn while it is still in my interrupt routine (e.g. between the last two instructions: and.b #$df,$ffff0a and rte) ? The register dump always shows that the last executed instruction was a clear of the interrupt pending bit, something like bclr #d0,(a0) with d0.b being 5 and a0 $ffff0a, in either the Xbtimer() or Jdisint() calls (I also tried to use Jdisint() before the next Xbtimer() call; same problem).

The current workaround I have is to revector the spurious interrupt and save registers, then call Xbtimer() and when the interrupt occurs jump back to retry (this is effectively a longjmp). The bios save area pointer is also restored. This works fine now, but I would like to know whether there is a less kludgy solution to this problem. Most programmers using Xbtimer() will not have noted this problem, simply because they use it only once (mostly I have to call Xbtimer() several hundreds of times before the interrupt occurs).

Leo.

From: AAron@image.soe.clarkson.edu
Message-ID: <1990Aug14.030733.21587@sun.soe.clarkson.edu>
Source record: 50440

Neither the PROGRAMMER'S GUIDE TO GEM or the MWC manual explain wind_calc()
very clearly. This may be what I need.

I have an object structure I created with a RCS, and I want to put it into a
window that fits around it exactly. I named the lowest (largest) box, and
found out it's width and height, and gave them to wind_create() to come up
with the correct size.

When I put my object into it, I lost the bottom of the object.
(I am clipping outside the window)

I have figured that NAME bar in the window is taking up space I did not count
on. I wanted to make the window the size of my object plus the HEIGHT of the
NAME bar, so that I can fit my WHOLE object into the window.

How do I figure out how big the NAME bar is?
(I want to FIGURE OUT how tall the window is rather than hard coding a height)
Or what is the easiest way of figuring out how big to open my window as?

> it's a file, otherwise it's a tty. Well in RTX, a handle could be
> a pipe, in which case it's not seekable, but it's not a tty either
> (it should be treated like a file).

The GCC isatty() code has a default return value of 0, i.e. if an
error occurs, it's assumed that the handle is not a tty. Thus, if
pipes give an error (e.g. -37, as they used to in RTX) and real ttys always
return 0 from an Fseek, then it can distinguish between them. This
might be a more robust scheme than doing the same thing for ttys and
pipes (it's the solution I chose for my multitasking system).

I presume the dLibs code does something similar, since there was a message
from someone (A. Pratt, perhaps?) describing this as the "official"
way to do isatty().

>>

It might be useful if someone would post Atari's suggested modification to the net, so that people who know about these things could evaluate and improve on it.

I have a question on the problem. I've seen several people in the UK mention it, but can't remember if the problem has surfaced anywhere else in the world. Maybe Claus Brod posted something about it, but I can't remember if it applied to Germany or if he was just trying to help UK users. Is the problem limited to the UK? I suspect not, and that the UK bias is mainly because of the way STEs have been distributed here in greater numbers. But if it is a UK problem (or even a European problem) then it might be due to differences between American and European/UK power supplies. (I'm probably just showing my ignorance here.)

The latest article I've seen on the problem in the printed press (From the UK ST Club newsletter) suggests that STEs should work OK with newer Atari Megafiles, but not with older ones, SH205s, SH204s and most third-party manufacturers' products. If I didn't know Atari were so under-resourced, I'd suspect a conspiracy. (Oops! This is straying from the 'tech' area. Sorry.)

102. embedding a data file in an executable

Newsgroup: comp.sys.atari.st.tech
Date: 1990-08-14 18:45:30 UTC
From: mroberts@oracle.uucp
Message-ID: <1990Aug14.184530.26793@oracle.com>
Source record: 50343

I'd like to embed a data file in an executable (.PRG) file. The idea is that, when the program starts running, it can find its name with the appropriate OS call (shel_read, I believe), open the executable as a binary file, seek past the load image portion, and then start reading data.

I've tried doing this the simple-minded way: figuring out how big the executable is, then hardcoding that size into the fseek(). This is just fine, until I actually append data to the end of the .PRG file. When I do, the program will not even load correctly, but bombs out with 3 or 4 bombs.

Does anyone have any ideas about how to do this? I have the impression that GEM is continuing to read the data that I append to the executable as though it were more relocation table data. After reading the Mark Williams C documentation and nout.h and gemout.h, and dumping the executable itself, I still don't have a very good idea about how the loader actually works.

Thanks,
Mike Roberts

|Or what is the easiest way of figuring out how big to open my window as?

It seems like you are confusing the total window area with the
work area part of the window (in which your object has to be drawn).

This is how to do it: use your object's sizes as the window work area
sizes (as you will probably know x and y can be determined by
objc_offset() and the width and height by using the OBJECT's .width and
.height members). From this you can calculate the true window sizes
using wind_calc(). Then you can create and open the window with these
sizes.

Here is how to use wind_calc() (as far as I can recall without the
docs; maybe I mixed up the order of wctype and winflags):

```
#include <portab.h>
#include <gemlib.h> /* For Lattice, your includes might differ */

WORD winflags = NAME|FULLER|CLOSER; /* for example */
WORD work_x, work_y, work_w, work_h,
win_x, win_y, win_w, win_h;
WORD retval;

/* Calculate work_.. from your object's sizes, then */
```

```
retval = wind_calc(WC_BORDER,winflags,
work_x, work_y, work_w, work_h,
&win_x, &win_y, &win_w, &win_h);

/* and now proceed to create and open using winflags and win_.. */
```

Wind_calc can also be used to do the reverse: calculate the work area sizes from the total window sizes; in that case WC_WORK should be used instead of WC_BORDER. The winflags are needed for GEM to detemine the window's accessories size (name/info fields, scrollbars), and should be the same as used in the subsequent wind_open().

Hope this helps,
Leo.

106. Floppies & Bombs

Newsgroup: comp.sys.atari.st.tech

From: flynn@clotho.acm.rpi.edu
Message-ID: <8W%%1L|@rpi.edu>
Source record: 50345

My fiance'e owns a 520ST with two floppy drives. Yesterday, both drives suddenly ceased working: click on A:, get '0 items', click on B:, get the same. Trying to format a disk resulted in the drive seemingly completing the formatting pass, then failing - immediately - on the verify pass. The day before yesterday, both drives were working.

Swapping cables doesn't help; removing one drive from the daisy chain doesn't help. Opening the CPU case and reseating things worked for a bit, then failed. In fact, she now gets eight bombs when she hits the power.

Any advice would be much appreciated!

Thanks in advance,
Flynn

From: tmp@doc.ic.ac.uk
Message-ID: <2190@gould.doc.ic.ac.uk>
Source record: 50351

Has anyone tried (or even considered) using blocks of four 256k simms to give
1Mb banks? Of course, this would require demultiplexing address line A9 into
two bits to select one of the 256k blocks within the 1 meg bank. Has this
be done? Is the ST's chippery able to handle the loading caused by the
simms being connected in parallel? (this would be a total of 8 per bank for a
4 Mb system, two groups of eight in parallel)
I'm sure this is a minefield of capacitance and timing problems, but would
like to know whether anyone has had any success.

A friend of mine is trying to upgrade his Mega 2 to four megs, but is having problems. Here's the deal. He plugs in the capacitors and sockets (I think this was probably a solder job). All the memory tests say that there's 4 meg available, but if he fills up a 3000K ramdisk, the programs past the first 2000K won't run. He's pretty sure that the problem is not with his MMU chip.

Has anybody had any similar problems or an idea of how to resolve this one? If so, please e-mail a response. He would be eternally grateful.

I've written a program which converts MacPaint format pictures to .IMG
format for use on the ST. I'll be mailing it to comp.binaries.atari.st just
as soon as normal service is resumed...

The present kludge of having to save two degas files using PICSW7 and then
trying to glue them back together seemed rather stoopid.

A friend of mine has a 520ST that upgraded by a true wizard to 1meg by
piggy backing 256K chips. You solder a second chip over the first.
It is amazingly difficult and you never know what will happen. It
often takes a couple tries, but it CAN BE DONE...

Somebody did. I got a copy somewhere of a german magazine (ST Computer ??)
which describes such a memory extension. Indeed there is some logic involved
to demux A9 and address the ram banks. Theoretically it ought to work, but
with all the added wiring and chip capacitance I think it stinks..

We have enough problems with installing "simple" 1 Mbit chips as it is.
(Well, not all of us, but according to this newsgroup frequent enough).

>Just what is Overscan anyway??? I have a 1040STFM with a 16Mhz Jato
>board, 4mb memory, and both a color and mono monitor, what if anything
>will Overscan give me?

Overscan is a hardware mod that lets you use more pixels per screen.
With a multisync monitor, I have 736x480 mono resolution, 832x280 med rez,
and 416x280 low rez. With an SM124 monitor you can get 688x480. With an
SC1224 monitor you can get 720x280 med rez & 360x280 low rez.

The complete docs with illustrations are available at atari.archive.umich.edu
for anonymous ftp. The files are in ~ftp/atari/utilities. o_scan60.arc contains
a version that is said to work for color monitors in 60 hertz mode. (I was never
able to get it working, but there may have been strange interactions with my
Turbo-16 accelerator board.) The regular version plus all docs is in overscn3.arc.

I included another version of the binary with my port of fractint 12. This
version traps the Xbios SetScreen call, to set the correct screen dimensions
when switching between low & medium resolutions. The other versions don't trap
this call, resulting in garbled text displays after switching rez. My version
also sets 50 hertz video mode automatically for color displays. Note that if
you do get the o_scan60 version working for you, your max vertical resolution
will be 224. I can live with the 50 hz screen, so I get a little more flicker
but also 56 more pixel rows.

This might be of interest to other net.users, so I am posting this
to the group...

The RamDisk that your frined is using is probably an ancient one -
90% of the RamDisks from the pre-Mega days break if you try to use
them with more than 2.5Mb of memory. Try C. Johnson's HRAMDISK,
it's a reset-proof ramdisk of the most excellent variety =:)

I cannot get gcc-cpp.ttp to run correctly under Micro-RTX. Under Gulam (TOS), I can type

gcc-cpp hello.c hello.i

and the pre-processed output goes to hello.i. Under RTX, however, I get an error (cannot create output file). This is a problem, since gcc uses temporary files for its passes. Can anyone help? I have the sources to gcc 1.37 from Terminator, but I have no idea on earth how to extract gcc-cpp from that mess to compile it on my ST.

By the way, does gdb work with gcc 1.37? I remember seeing a message claiming that it did not, but it was a little confusing. Thanks.

Leo -

Just as a guess, sounds like your interrupt is ocurring at the same time you are attempting to change it. Just some observations:

1) Be certain your interrupt is restoring any registers it destroys
2) Be certain _not_ to save registers onto the stack, but rather use a static storage area
3) If neither one of those help, try masking off interrupts by raising your ipl to 7 before issuing the xbtimer() call. From what I can see of the xbtimer() call, it does not touch the ipl when it is initing the mfp, so you can conceivably be interrupting when you are changing. Altho, the xbtimer() call does disable the interrupt before changing it...

[...]
>By the way, does gdb work with gcc 1.37? I remember seeing a message
>claiming that it did not, but it was a little confusing. Thanks.

Yes! GDB works fine with gcc 1.37.1 (I got mine from dsrgsun.ces.cwru.edu [129.22.16.2]). It is a little confusing at first, though. Basically, you have to go through these steps...

1) Write your c source (the easy part <heh>).
2) Use the -gg switch when compiling and make sure the pre-processor symbol __NO_INLINE__ is defined (either in source or on command line):
gcc -c -gg -D__NO_INLINE__ file.c
(Hmm, maybe I/someone could put the NO_INLINE bit as default for -gg in gcc)
3) After you link, you need to make a special symbol file with sym-ld. Use the -r switch, and specify the modules in the same order (I think). For that reason, I like to link explicitly, and not trust gcc to do it:
gnu-ld -o a.out \lib\gcrt0.o file1.o file2.o -lgnugdb
sym-ld -r -o a.sym \lib\gcrt0.o file1.o file2.o -lgnugdb
You can use the "gnugdb" libs if you have them, but the plain "gnu" works too (sometimes you can get lost in the libs, and library calls with invalid parms are hard to de-code). Of course, use gnu16 if you're a -mshort person. Okay, now for the fun part.
4) Invoke GDB without arguments.
5) Load the executable and symbol files:
exec a.out
sym a.sym
6) Start the program, setting args if appropriate
set-a argv1 argv2
run
7) GDB will automatically stop at the top of your program, so set yer break points and squish some bugs!

We should all give our deepest appreciation to the folks who made GDB work, by all accounts it was a massive ugly hairy beast from the depths. So THANK-YOU jrd (and John Dunning for a sweet debugger, too)!

>David Megginson
>david@doe.utoronto.ca
>meggin@vm.epas.utoronto.ca

Jon McCarty
(internet) jmccarty@ucsd.edu (bitnet) jmccarty@ucsd

P.S. GDBM works in 32 bit mode, anyone tried -mshort on it? how about
the new version (1.4?)?

|Leo -
|
|Just as a guess, sounds like your interrupt is ocurring at the same time you
|are attempting to change it. Just some observations:
|
|1) Be certain your interrupt is restoring any registers it destroys

Yep, it is _very_ simple (also in order to have a fast counter):

```
myint
add.l #1,counter
rte
```

|2) Be certain _not_ to save registers onto the stack, but rather use a static
| storage area

Does not apply here.

|3) If neither one of those help, try masking off interrupts by raising your
| ipl to 7 before issuing the xbtimer() call. From what I can see of the
| xbtimer() call, it does not touch the ipl when it is initing the mfp, so
| you can conceivably be interrupting when you are changing. Altho, the
| xbtimer() call does disable the interrupt before changing it...

Ah, but the spurious interrupt does indicate problems with the MFP, not
with the 68000; if I understand correctly, it generally indicates that a
BUSERR occured on a periferal chip. So masking all interrupts shouldn't
help (but it won't hurt to give it a try).

In your second note:

|Also, 24 bombs is not real. Chances are you are getting 2 or 3 bombs (address
|error (3 bombs) or BUSSERR bus error (2 bombs)) but repeatedly. In other words,
|the system crashes, attempts recovery, crashes again, etc. until it locks up.
|
|Well, 24 bombs is real, but I've never seen it occur...

But it is most definitely exception 24 (spurious interrupt); this is
not only indicated by the ST bomb thrower - which occasionally is
unreliable - but also the exception save area indicates this. And
catching vector 24 and retrying does solve the problem ...

B.T.W. thanks for your suggestions, Mike. If someone is still
interested, I'll try to cut out a minimal code fragment to hack on.

This has been done in the German 'ST' magazine, using DIPS rather than simms. A freind of mine over here has implemented this solution - on an ST520+ we had to use a small electric saw to remoce the old on board chips, meaning we that we could then desolder the individual pins, rather than the whole chips. This significantly reduces the risc of dammaging the motherboard. we could then solder in modified sockets, and then insert the piggy backed dips. Some flying wires were needed to give adequate earth shielding, which proved to be the downfall of this experiment. The system ran OS9 with one user on a terminal for about a week without any problems. As soon as the holidays were over and the owner of the ST began to log in on the console, which was in a room locked during the break, problems with timing began - We thought there might be standing waves in the earth lines, which being wire, as apposed to perfect conductors are of course not at earth anyway! The fact that the system worked single user was because only a small address range was used, and refresh hardware could cope with the problem, whatever it was. As soon as multi user (multi tasking) resumed, the standing waves or whatever canceled the refresh signals or something allong these lines...

We replaced the Earth wiring with shorter connections, and more of them, and the problem went away... for about two weeks. The 520 has its Store ("memory" to lusers memory is cache/associative store. Store is anything else) directly beneath the keyboard. As time went on, the connections worked loose and all the wonderful work literally fell to pieces. Two sessions of soldering on the modified sockets allowed the soldered modifications to work loose, adding to the death of this

otherwise nice modification to an ST.

We then bought a locally made addon board, and transfered the chips to it. This has been working perfectly ever since (4 months) despite the computer having been moved several times.

I will post more details about the memory expansion board as soon as I can find the comercial address of the firm in that heap of unsorted papers called my desk.

If you want more details about hacking it yourself, send Email to me, and I will try to get a copy of the construction details of the 'ST' magazine circuit to you.

Happy soldering, and dont let Farraday catch you unawares!!

Andrew Miller

From: John.Bunch@samba.acs.unc.edu
Message-ID: <877@beguine.UUCP>
Source record: 50366
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

Hello all,

I just recently was given an atari 1027 printer, and would like to know if it is possible to hook the beast to my ST? I realize that it may require building some sort of adapter so the st can talk to the SIO port on the printer. Has anyone ever attempted such a thing? Is it possible to do? And If you not sure, do you know where I may be able to get the manual for the printer? It was given to me without a manual and without a power supply...

From: grahamt@syma.sussex.ac.uk
Message-ID: <3300@syma.sussex.ac.uk>
Source record: 50370

Could someone give me some tips on how to save (& of course load) configuration information to the program that uses it, while running that same program? I've seen lots of programs that do this - e.g. Charles Johnson's Little Green Selector & Arcshell, the Universal Item Selector, etc., and I'd like to do this myself.

I've written a program (in Laser C) which sends various settings to my printer. It runs either as a .PRG or as an .ACC (I used Samuel Streeper's init file), and it uses a dialog box as its user interface. At present, the program sets the defaults I like (e.g. elite, draft, skip 4 lines at perfs, A4 page size) at startup time. I'm aware that my preferences aren't everybody's, and I'd like to let other people set their own defaults.

My options are either to read from / write to a separate .CFG or .INF file, which I could do but would rather not (I've incorporated my resource file info into the main program file and I'd like to keep everything in a single place if possible), or save the info directly to the program itself. How is this done?

Thanks in advance.

Graham

I guess the header (Subject & Keywords) say most of it.

I recently got the cpm emulator for the ST and installed it on my system.
Following directions, I'm supposed to format a single sided diskette
and type make_cpm. This make a CPM diskette OK but the next step is to
boot up CPMZ80.TOS, insert the disk I just made and after following
the prompts and getting a A: prompt, I'm supposed to type INIDSK a:
The proble is that when I insert a freshly TOS formatted disk (or any
for that matter) I get a 'DISK NOT EMPTY' error and inidsk aborts.
That's one error. Another is that according to docs, the TOSCPM
utility is supposed to copy from drive a to drive a prompting for
diskette changes. When I try, I get an error stating something like
'SOURCE and DESTINATION disks are the SAME' then aborts.

Well, I give up! I am running TOS 1.4. Could this be the problem?

Any help or hints would be appreciated!

THANX in ADVANCE, Paul Moreau.

You need to either get a new set of binaries (avail on picasso.ces.cwru.edu or dsrgsun.ces.cwru.edu) or compile all the executables again, using a newer version of the library startup file crt0.c (library Patchlevel 56 or better). The problem is with RTX that does not follow all the atari rules when launching an application (specifically clearing A0 on an application launch vs. A0 == basepage for an Acc launch). This newer crt0.c does'nt depend on this fact any more (to detect acc startup) and works just fine with RTX (and others like PACK etc).

> sources to gcc 1.37 from Terminator, but I have no idea on earth how
> to extract gcc-cpp from that mess to compile it on my ST.

Huh? Just look at the supplied makefile.

>By the way, does gdb work with gcc 1.37? I remember seeing a message
>claiming that it did not, but it was a little confusing. Thanks.

yes, its true. gdb doesnt work with gcc 1.37. in fact -gg support has completely disappeared from the new version of gas (1.36) (this newer version is available from dsrgsun/picasso.ces.cwru.edu for both minix and tos).

cheers,

Howdy all,

Me again.. I would like to know if anyone out there has the pinouts
for the atari 1027 printer? I would like to connect it to my st.

I understand I am gonna have to build some sort of connectory to
hook the SIO to a standard parallel port.

John

P.S. Please reply via email and I will summarize to the net.

>the program itself. How is this done?

It's easy enough to rewrite bytes in the middle of the .prg file using
the Gemdos functions Fseek and Fwrite. Your only problems are to find
the file (not so easy) and to figure out which bytes to change.

I don't know of a reliable way to find the name and location of the
.prg file which is currently running. It will often be in the default
directory on the default device (depending on how the program was
invoked), but it doesn't have to be. The Pexec that invokes your
program probably leaves this information behind in some undocumented
memory locations somewhere, but you can't count on that not changing
in the future.

The second part is easier. Declare all of your configuration
variables at the top of your program as static, and initialize them to
appropriate default values. This should cause the compiler to place
them at the start of the data segment of your program. Information in
the header of a .prg file tells the lengths of the text and data
segments. Read that information and calculate the position in the
.prg file of the start of the data segment. Seek to that position and
rewrite your variables. To be on the safe side, put a magic number as
the first thing in the data segment and check that it is there before
you start writing. This may save you from clobbering the wrong file.
Thus, your program might start as follows:

```
static char magic[8] = "myprogxx";
static int width = 85;
...
```

Hope this helps.

135. STFM 2 Meg upgrade

Newsgroup: comp.sys.atari.st.tech
Date: 1990-08-22 12:56:46 UTC
From: ccsams@gdt.bath.ac.uk
Message-ID: <1990Aug22.125646.13863@gdt.bath.ac.uk>
Source record: 50377

This is a plea for help. I have a 520STFM to which I want add more memory. I know how to add another 0.5 Mb, using the otherwise-empty ram bank, but I want to add 2 Mb (the maximum a bank can take) instead. This is where my problem begins, as I don't have all the technical information necessary to tackle a 2 Mb upgrade.

The 0.5 Mb upgrade uses 16 41256 DRAM chips, which are 262144 * 1 bit. If I was to use 16 511000 DRAMs instead, I would have 16 * 1048576 * 1 bit = 2 Mb. But the 41256 and 511000 do not share the same pin assignments, or number of pins. So I can't simply plug in 511000s where the 41256s would have gone.

The pin-outs of the 41256 and 511000 look like this:

```
--------U-------- --------U--------
A8 -=| 1 16 |=- GND Din -=| 1 18 |=- Vss
Din -=| 2 15 |=- /CAS /WE -=| 2 17 |=- Dout
/WE -=| 3 14 |=- Dout /RAS -=| 3 16 |=- /CAS
/RAS -=| 4 13 |=- A6 NC -=| 4 15 |=- A9
A0 -=| 5 12 |=- A3 A0 -=| 5 14 |=- A8
A2 -=| 6 11 |=- A4 A1 -=| 6 13 |=- A7
A1 -=| 7 10 |=- A5 A2 -=| 7 12 |=- A6
Vcc -=| 8 9 |=- A7 A3 -=| 8 11 |=- A5
----------------- Vcc -=| 9 10 |=- A4
-----------------

41256 511000
```

As you can see, both chips have the same set of functions, except that the 511000 has an extra address line A9. It is possible (though messy) to wire up a 511000 to make it look like a 41256 to the ST's circuitry, but what should I do about A9? Can I wire it to somewhere on the ST's PCB? If so, where? The MMU perhaps? Which pin? Would the ST be then able to use the new RAM without any other modifications? Are there any wire links and/or resistors in the ST's circuitry which tell it how a RAM bank is configured? If so, what change(s) would I need to make to them?

Any information relating to the above would be greatly appreciated. Maybe there is a different and altogether better way of adding 2 Mb. Incidently, is the pin-out of a 511000 the same as that of a 41000?

Thanks in advance.

Alan Skirenko.

>the program itself. How is this done?

I don't know of a reliable way to find the name and location of the
.prg file which is currently running. It will often be in the default
directory on the default device (depending on how the program was
invoked), but it doesn't have to be. The Pexec that invokes your
program probably leaves this information behind in some undocumented
memory locations somewhere, but you can't count on that not changing
in the future.

If the program is launched by the desktop, you can find out it's name
and path by calling shel_read. This function expects two parameters:
the first array of characters is filled with the path of the current
program, the second array of chars will contain the arguments supplied
by the TTP-box or the "Install application"-feature.
If your program is launched by some shell, you could look at argv[0]
supplied by one of the extended argument passing methods (eg. xArg or
ARGV environment vars). You could also search for your programs name
(obtained from argv[0] or your default name) in the directories
specified in the PATH environment variable.
As a last resort, you could prompt the user for the location of the
program.

Hope this helps.

- Edgar

137. Need Real Time Clock or Schematics

139. Working on an acc. (was: window size stuff)

Newsgroup: comp.sys.atari.st.tech
Date: 1990-08-23 00:13:30 UTC
From: AAron@image.soe.clarkson.edu
Message-ID: <1990Aug23.001330.9981@sun.soe.clarkson.edu>
Source record: 50378

In trying to get my object inside a window, I have gotten helpful response:

From article <884@ehviea.ine.philips.nl>, by leo@ehviea.ine.philips.nl (Leo de Wit):

[Stuf. del.]
> Here is how to use wind_calc() ...
[Stuf. del.]

Great, I'll check out your solution also!
I have gotten responses from gt1448b@prism.gatech.edu, cmedley@wam.umd.edu
and sstreep@NeXT.COM also.

And I have had success using a form_center() then feeding it's results into
wind_calc(), and everything ends up centered, and fits correctly inside the
window's workspace.

I can even move it around, update it correctly (most of the time, but I will
question this later), but now I have a different problem.

****New problem:
I have created my own sliders and buttons inside my object, and would like
to know how I figure out when the user is clicking/dragging them.

I tried a form_do() (because I had used it before, and had success), but
being a desk accessory you can probably guess what happened. It demanded
that I do something with my object, and wouldn't let me move or close the
window it was in, or other stuff desk accessorys are supposed to let you be
free to do....

My desk accessory resembles to some extent the control panel.

It is the STe sound panel, and it will get posted (source and all) as soon
as it is working)

140. Something is WARMING in my Mega

Newsgroup: comp.sys.atari.st.tech
Date: 1990-08-23 07:33:30 UTC
From: jackin@vehka.uta.fi
Message-ID: <1514@kielo.uta.fi>
Source record: 50379

I seem to have problem with my Mega. After a few hours work
my Mega (2) starts to act weird. Few of the symptoms :

- ususal crashes with 2,4..30 (or so) bombs
- screen goes white, but the program is still working
only I can't see it. If the program updates screen/window etc.
it will be OK for a while.
- there are other, but as I usually go very near of nervous
breakdown when these things happen my mind mercifully forgets
them :-)

The time before weirdness starts is relative to the space between the
Mega and my desk (more airspace, more time).

Any suggestions ? I can replace quite a few components myself and if
I can't my friends can.

Thanks,
Markku (jackin@vehka.uta.fi)

141. Malloc() and desk accessories

Newsgroup: comp.sys.atari.st.tech
Date: 1990-08-23 20:01:56 UTC
From: steve@thelake.mn.org
Message-ID: <A2017203479@thelake.mn.org>
Source record: 50381

I've seen comments to the effect that calling Malloc() from a desk accessory is a Bad Thing, and I wonder if that is always true.

I want to write a desk accessory that will filter ASCII text into a format suitable for Pagestream. The Pagestream ASCII import function is brain-damaged -- it will not properly handle normal text with hard returns at the end of each line and paragraphs separated by a blank line (which is what you're reading right now).

I want the DA to
wake up from evnt_multi
get a filename using fsel_exinput
compute the file size
open the file
Malloc() enough memory for the whole file
read all of it into the buffer
strip line enders (except blank lines)
write the modified file back to the disk
close the file
Mfree() the buffer
return to evnt_multi

There would not be a chance for an application to terminate while the allocated memory was being held. If the memory allocation follows the same rules as file handle ownership, there would not be a problem. True or false?

My Mega 2 had the very similar problems from the start, especially on warm days. I "solved" the problem at first by allowing lots of air space around the computer. When the 6-chip TOS 1.4 ROM set was installed the problem could no longer be ignored. The dealer solved it by replacing some low-power Schottky drivers with some standard Schottky drivers. Sorry, it's been about a year and I can't remember exactly what parts were replaced. It did fix the problem "for good", though.

From: johns@maccs.dcss.mcmaster.ca
Message-ID: <26D46538.12976@maccs.dcss.mcmaster.ca>
Source record: 50385

Looks like it's time for me to get a hard drive. I've heard about
people who have built their own, and I could use some advice.

I'm looking for a combination of removeable and normal internal
drive. A fast access time is nice, but not the most important thing. I'd
like to be able to hook up a laser printer as well. Ideally there would
be room in the case to put a floppy 3.5 inch drive.
What combination of host adapter+software, controller, mechanism,
and power supply would be optimal for this kind of hard drive setup?
Another question: anyone heard of the MASTER 3S external floppy
drive distributed by Konyo international?

Thanks for any advice. If anyone wants a summary of info I get
I'll be happy to forward what I learn.

147. Desk Accessory memory allocation (over-consumption)

Newsgroup: comp.sys.atari.st.tech
Date: 1990-08-24 04:02:43 UTC
From: moses@hao.ucar.edu
Message-ID: <8316@ncar.ucar.edu>
Source record: 50387

I have created a relatively large desk accessory program for the ST
using GFA BASIC, and the problem I am having is that TOS is allocating
twice as much memory as is needed for the accessory.
Adding up the executable file header information and also the
Malloc calls, used for buffers, to get a total memory requirement and
also having used as few global variables as possible, there is a memory
requirement of ~170 Kbytes. But TOS is handing over 325 Kbytes of memory
to the desk accessory.

IS THERE A WAY TO REDUCE MY D.A.s MEMORY CONSUMPTION? TOS AUTOMATICALLY
SHRINKS MEMORY FOR EACH D.A. BUT APPEARS TO DO A POOR JOB OF IT.

Thanks for the help.

148. Multitasking system now available for beta test

Source record: 50388

A beta test version of MiNT (MiNT is Not TOS) is now available at
atari.archive.umich.edu, in the file mint05.zoo. MiNT is a multitasking
extension for TOS. It comes with complete C source code and is freeware
(but *not* public domain -- see the docs). Some of the features it has
are:
pipes, pseudo-ttys, named FIFOs, BSD-like signal handling, fork() and
vfork() system calls, job control, special pseudo-drives (for accessing
FIFOs, BIOS devices, and processes -- you can delete or rename a process
by doing the appropriate thing to the entry on the pseudo-drive), and
other Unix-like features.

Since this is beta-test software, I would caution you to get it only if
you're a reasonably experienced programmer. I will be posting MiNT
to the sources and binaries groups sometime in September, if all goes well;
in the meantime I would be very interested in hearing of any bugs
and in suggestions for improvements.

Hello....

I seem tro have a problem with my st. I was using it last night
and all of a sudden I could no longer access the floppy drives...
So I shut it off and tried rebooting. I still could not access the
drives. The weird part is when it boots up, it recognizes the drives being
there I just cant do anything with them? It always boots in low res
and I tried creating a folder on the disk and was not able to. Also
when I opend a window with a directory it showed me nothing.... I am
fairley sure it is not a problem of the drive, because I have two and trie
hooking them both up alone and got nowhere. Anybody got any clues?

I think it may be the DMA chip?

heh, heh, heh. I haven't seen this one in awhile. If you're getting windows
that say 0 bytes used in 0 items, you probably need the "drop test" fix.

Early STs had trouble with chips coming unseated. To fix the problem you
describe, you can generally either open up the ST and reseat the chips (DMA
chip only?) or you can pick it up about an inch or two off the table and
drop it. That fixes my sister's ST every time.

--Steve

P.S. You might also try a different cable... I've had trouble with one before.

Sorry, Derek! That's exactly what I meant, but I also meant ST BASIC... not
Atari BASIC. I'd like to write native ST stuff for the 1020. What the heck?
I have to waste my time on something...

>Is it possible to use the xformer cable, and not the xformer?
>I would rather not have to run the 8bit emulator to print stuff.....
>

Yes it is _possible_ to have ST software use the Xformer cable directly. However, there is very little software out there that knows how to use the Xformer cable. It isn't quite possible to access it, like, say, an ST printer or modem. What software there is out there to use the cable is stuff like my Quick Transfer Utility, which transfers over 8-bit disks to the ST for the purpose of later using them with Xformer, and then there is another program out there which someone else wrote which allows you to use your 8-bit disks drives with GEMDOS, although this is a really slow alternative to simply buying a second ST drive! And besides, if you're going to write some new application that will make use of the Xformer cable, then just write it in Atari BASIC or 6502 assembler.

Other than that, to use the Xformer cable to access 8-bit peripherals from other ST software, you would have to write your own driver. It's actually not that hard, since I wrote the bulk of Xformer's cable driver in one night. I have had other people request that I write a printer driver along the lines of what you're looking for, but I simply don't feel such a driver needs to be written. What's so hard about simply printing out files from within Xformer? Running Xformer is easier than running, say, an MS-DOS emulator or a Mac emulator, and people have gone through a lot more trouble to get something printed out on those emulators.

So as far as I'm concerned, my suggestion is that whatever you need to print out, print it to a file (e.g. if you're using a word processor, have it print to a file) and then run Xformer and use Atari DOS to copy the file to the P: device, then exit Xformer. The whole operation (not including printing time) takes less than a minute. Try booting up and exiting an MS-DOS emulator in a minute. I'm sure if it was really worth my while ($$$) I could be motivated to write the beast, but that's probably not going to happen.

156. ICD adapter problems

Newsgroup: comp.sys.atari.st.tech
Date: 1990-08-27 21:13:07 UTC
From: cs63bld@unccvax.uncc.edu
Message-ID: <2641@unccvax.uncc.edu>
Source record: 50296

I have an advantage-plus scsi adapter with built in clock for my
atari 1040st. The hard drive side of it works fine but the clock
is a crock!

Here is the description of the problem:
If there are any desk accessories on the machine, and you warmstart, the
system time will lose about 10~20 sec. This happens every time warmstart
occurs. Thus the clock is soon terribly wrong. If there are NO desk acc
(not even one) the time will be fine. The system time is updated by
a program callled ICDTIME.PRG that you are supposed to put in your auto
folder. However, if you do not put ICDTIME in your auto folder, but instead
wait until the system has booted and run it from the desktop, everything
works fine even with desk acc.

I was planning on writing my own time update program to get around this,
but upon calling ICD about the problem, I was told that they had never
heard of this, didn't really believe I was describing it properly, and
no, they would not tell me how to access the clock directly.

Any help would be greatly appreciated, even if it is only to tell me
that you have the same problem but don't know how to fix it...I'd at
least know that someone else has to put up with it :-)

PS-if you can explain to me how to access the clock directly, that would
be great too...

As a final note, after the attitude I have had to put up with from ICD
tech support, I wouldn't reccommend you buy a hard drive adapter from them.

Thanks in advance,
BRian
(cs63bld@unccvax.uucp)

- PS-if you can explain to me how to access the clock directly, that
- would be great too...

I think the SCSI ID for the clock is #6, but I don't think that helps
you much.

There is also a program usually supplied with their software called
TIMESET.PRG (or something like that). It gets the tiem and date from
the clock when it's run, but then leaves memory. You can't set the
time with it. I use it from the AUTO folder instead of ICDTIME.

BTW, there's also a nice clock setter for the ICD host called
ICDCLOCK. It's written for mono monitors but is readable in color.
No, it's not written by ICD Inc.

Hope this helps.
```

Source record: 50299

You are right.The first ICD card did the same thing but had a pot
on it that I could adjust to compensate. If you check back with ICD
at a later date they will probably have a fix for it posted. I had
a problem with their early software park.prg which set the date to
1992 every time it was run and they fixed it after about a month.
Their support is OK as far as I've seen. An alternative is to use
the other ICDTIME.PRG that disappears after setting the system clock.
This means you cannot set the time with the control panel, but do you
really need to reset the clock on the ICD card after the time has
been loaded into the system? Well you might if the time is off.
Mine isn't off that much to get excited about. If you look at the
card you received you will see a crystal that is the clocks timing
circuit. There will also be a trim capacitor and resistor. If you
notice the time is off after a period of time (about a month) you can
try changing the battery first, then trimming up these (res. or cap)
to change the crystal freq. into the clock chip on the ICD card.
Their (ICD's) updates are free if you register on their BBS and their
records indicate that you have purchased their hardware. You pay
for the call but it's the best software update system I've seen for
the ST next to Laser C's from Megamax. You can just download the
software that has changed if you want or the entire new archived
system. I don't think you get access the first time you call, they
need time to verify you with their records (warranty card?). Hope
some of this helps you out.

>is a crock!

There are problems with the ICD clock when used on older ST's.
Something with bus noise problems. ICD has a hardware solution. There
is a simple to install daughterboard for the ICD Advantage Plus.
Installation is explained by a simple flyer that comes with the fix.
What you do is remove a chip from a socket on the ICD board, I believe
it is U4, and then you plug this small daughter board into the open chip
socket. Simple as that! If you need one of these boards, you can call
ICD for one.

My clock was screwy as anything until I installed the fix. Now
my clock works fine. I set it over TWO (2) months ago, and it is still
accurate!

I use the ICDTIME.PRG (the one that sets the clock and remains
resident) ONLY to SET the clock. I boot it from the desktop if I want
to set the time. Then I cold boot to get rid of it. I don't trust it.
I use the GETTIME.PRG (or whatever it is called... the 600 or so byte
file that just reads the time) from my AUTO folder to set my time at
boot up.

I own the ICD Advantage Plus as well as 2 of my friends, and all
three of our clocks now WORK BEAUTIFULLY! Love that clock!

Hope this helps,
Jim Tauberg

162. Re: Malloc() and desk accessories

Newsgroup: comp.sys.atari.st.tech
Date: 1990-08-28 19:28:55 UTC
From: kbad@atari.UUCP
Message-ID: <2261@atari.UUCP>
Source record: 50302

As long as you don't go back into an event wait, you can Malloc all day long (Mfreeing what you Malloc when you're done with it, of course).

The only time DA's have Malloc headaches if they try to Malloc memory outside their startup sequence is if they give the parent application a chance to terminate out from under them. The problem arises when an application calls appl_exit(). The AES does not give DA's enough time to clean up after themselves before the parent application's resources are released. It is possible for a DA to not get an AC_CLOSE message until you're already back at the desktop.

Note that this also causes problems with DA's that open virtual workstations, since the VDI Mallocs memory for workstation information.

A sequence of events like the following could cause problems:

Run an application.
Open a DA that opens a workstation or Mallocs some memory.
Quit the application without closing the DA.

At this point, the application calls appl_exit(), which returns before giving all DA's a chance to clean up. The application then terminates, and GEMDOS frees all the memory that was allocated while the program was running. Eventually, the AES will get around to telling the DA, "Oh, by the way, shut yourself down now." If the DA then tries to access any of the memory it had Malloced, it would be messing with memory that had already been freed. If this memory had since been reallocated, the DA would be changing someone else's memory. If it happened that the memory had been reallocated to someone else _at the same starting address_, it would be disastrous for the DA to Mfree that block.

The solution is simple. DA's must only Malloc memory in an atomic (from the AES's point of view) operation, as Steve outlined. If a DA has more dynamic memory needs, it can allocate a heap for itself at startup, BEFORE IT MAKES ANY AES CALLS. The DA can then use it's own memory management within this heap.

Thanks for the explanation Ken. Would using an auto program to serve DA memory requests work? Could the auto program somehow wake up once Gem was initialized so it could use the gem pipeline to get requests for memory from DA's and attach them to it's basepage. If this worked,it would seem we could have one auto program handle requests from many DA's. I know this is off-topic from Steve's question,but I'm curious. Actually,I'd guess this is how the non reset proof version of Shadow works.

Thank you for any help

vovut@prism.cs.orst.edu

==========

Suggest you look at the SmartWatch, DS 1216E device. There is software in the ST realm written by a fellow named Bill Penner from out your way in Oregon or Washington.

This is a Real-time clock which fits under any ROM socket. The Areal software (version 3.3) will look for the SmartWatch in any of the possible ROM sockets. Hope that helps.

>> The 410 is a WRITE ONLY device...
>You are wrong. It can be read and written to. It'd be worthless
>otherwise!

I was also told in private email that the 1010 should be a R/W device...

Nope, even the 1010s ADVANCED circuits only allows a WRITE ONLY device...
The 1010 IS good for expanding your SIO cabled device chain.

I took an extra SIO cable... like from a disk drive... and I cut it in half
and I soldered the wires onto the two female jacks on the 1010...
one connector per femal jack--> in the end, I had a 1010 with 2 female
ports and 2 male ports (And no, I am NOT going to tell you why I found
this so incredibly useful.)

Note 1: The 410/1010 are WRITE ONLY devices as APL is a WRITE ONLY language.
Note 2: GET IT? A JOKE? What? Wrong news group? :-)
I could write with my 410/1010 fine... but when I tried to READ one of those
tapes.... I got into the habit of storing my files on paper and retyping
them wheever I wanted one. I still have 4 410s... and 1 1010.

(I'm not Ken, but...)
I would say not. There's no way to "wake up" a TSR under TOS; from TOS's
point of view the program is dead and buried. If you want to go for
non-portable code, the desk accessory certainly could dig through the TOS
memory allocation list and "attach" any memory it allocates to some other
program that won't terminate (the desktop being an obvious candidate).
This strikes me as being quite ugly, and moreover I'm not sure that it would
be guaranteed to work.

Your suggestion of having a "server" handle memory requests from DA's would
work quite well under a multi-tasking system such as RTX or MiNT, and should
be easy to code under either of those two systems.

Netlanders,

I am going to upgrade my Aerco board from .5M to 2M. All I need is
the 1Mbx1 DRAM chips. My question is: Do I need to get relatively fast
chips or is it not going to make any difference for a 68000 system? If
anyone has any experience in this area, I would appreciate the help.

Thanks,
Ric

P.S. I'm looking to get 120ns Intel DRAMS @ $6 if they don't need to be
any faster.

>This strikes me as being quite ugly, and moreover I'm not sure that it would
>be guaranteed to work.

There is a trick that will work (at least in TOS 1.4) but is also not
portable. Namely, change the current process pointer to point to the
DA before doing the Malloc, and restore it to its original value
immediately afterwards. This causes Gemdos to think that the DA is
the owner of the newly-allocated block, not the currently-running
application, which is what you want. The current process pointer is
kept in a documented low-memory location. What isn't officially
sanctioned is changing the pointer; it is supposed to be read-only.
Thus, the behavior of TOS when you change it is not guaranteed to be
the same in future versions of TOS. Another warning besides the
non-portability issue: memory fragmentation can become a real problem
if DA's go around Mallocing memory at random times. What Ken
described is much safer.

171. TOS 1.4 question

Newsgroup: comp.sys.atari.st.tech
Date: 1990-08-30 03:12:07 UTC
From: hyc@math.lsa.umich.edu
Message-ID: <1990Aug30.031207.396@math.lsa.umich.edu>
Source record: 50312

I've discovered part of the reason for SwitchBack not working on my system now... SwitchBack is activated by the Centronics busy interrupt, which worked fine on TOS 1.2, but it seems that TOS 1.4 likes to keep masking this interrupt off. Every time a program is Pexec'd the interrupt is masked off again. I've done a little snooping but haven't found the culprit just yet. Anyone out there recognize the feature?

One other problem I've had is due to Turbo16. The SwitchBack interrupt handler uses two delay loops to validate its invocation. (Load register with counter value, dbra to itself. Wait for port bit to raise, wait longer for it to reset again.) The loop doesn't wait long enough for the bit to reset, so the handler always returns without doing anything. I doubled the counter value, and things are closer to working now. But, more often than not, after typing a command key I get bombs and a total lockup.

>topic from Steve's question,but I'm curious.

hmm... Interesting idea, but I doubt you'd get any better results. You'd
have to hook into the evnt_multi or evnt_mesag handler or even hook into
the appl_write handler and fake a waiting event or entirely intercept the
appl_write call... Too much trouble, but interesting concept.

>Actually,I'd guess this is how
>the non reset proof version of Shadow works.

Not actually... For what you suggest above, tho, a similar handler to Shadow
could be implemented for DAs. It would require your intercepting the Malloc()
call from Gemdos.

What Shadow does is change the p_run pointer to it's basepage before mallocing
a buffer, then switches it back to the value before. p_run is the current
process basepage pointer. It's location is documented for TOS 1.2 and greater.

Source record: 50311

This is posted for a user of a BBS I run:

I understand through the grapevine that sometime next year there MIGHT be some dRam dumping from Japan. So it is time for me to think about doing a memory upgrade for my old unexpanded 512K machine.

I *_*THINK*_* I have figured it out using 256Kx4 devices, which would necessitate only 4 devices. However, I might want to look at using 1Megx1 or 1Megx4 devices instead. Has anyone done any preliminary work on this?

Also.... I seem to recall some information about jumpers to tell the MMU what RAM devices are being used. Does anyone have any information about that? If not, how does the system tell what amounts of RAM are available?

From: tmp@doc.ic.ac.uk
Message-ID: <2222@gould.doc.ic.ac.uk>
Source record: 50314

Hi,
I don't want to start the thread on the 'phantom typist' going at full pelt again, but I seem to have a problem of this kind on my ST (although I'm not sure if it is the same as the problem described by most posters).

What happens is that after a bit of high mouse activity (usually on the desktop) the currently open window continually updates - this is as if the ESC key is being continually pressed.
The best way of stopping this, I have found, is to go to create a new folder. When I do this, the cursor on the text line is flickering like mad - all I do is to backspace until it stops (clearing the buffered characters?) and cancel, which is ok until it happens again.

When this hits during an editing session, usually the character '1' or sometimes '2' continually appears - again backspacing stops this if I catch it in time.

In an attempt to isolate the cause, I have tried changing the IKBD processor, bought a new mouse and dismanteled the keyboard to look for grot around the ESC, 1 & 2 key contacts. The solder on the mouse socket is ok as well.
The problem occurs without any DAs or auto folder programs.
Strangely, it only started after I installed one of those keyboard clock battery backup boards, but has stayed since I removed it. (the keyboard processor was changed after this)

My ST is an STFM with 1985 ROMs. Any suggestions? (other than 'buy an STe' :) please email me if possible.

Cheers, Trev..

I hadn't thought of that trick; it's not a bad idea. As you say, though,
it may not work in future versions of TOS. It certainly doesn't work
under MiNT (which sets the current process pointer, but otherwise ignores
it). I don't know about RTX, but I'd suspect that it would have similar
problems.

Why is it that every time someone comes along to patch one of the TOS functions, they have to intercept the trap handler? I've been thinking about writing an AUTO folder program that basically copies all the BIOS, XBIOS, etc. jump tables to RAM, so you don't have to duplicate all the effort of intercepting the call, testing the function number, etc. (i.e., the program has a functional duplicate of the current BIOS/XBIOS trap handler, but it uses a jump table in RAM. When you want to replace a function with your own, you just need to change the jump table, not install a brand new trap handler.)

Why didn't anyone ever do this before?

The program could be very stupid, and just have the jump tables for each version (1.0, 1.2, 1.4) of TOS hard coded, or it could be very incredibly smart, and walk thru the existing trap handler until it encounters the magic jump instruction, and duplicate things that way. Either way it would make later changes much more convenient, no?

The last thing you want to do to get rid of this problem is buy an STe!

My STe does this 'phantom typing' thing a lot. It sometimes appears as if
the escape key is being help down and other times it's the left mouse button.
I've noticed that this often happens after moving the vertical slider bar of
a window on the desktop. I've never tried to figure out exactly what causes
this and I can never make it happen (with frantic mouse movement etc.) on
demand.

I don't know if it's caused entirely by the STe or by software that I use
(eg. mouse accelerator etc.) but it DOES HAPPEN on the STe.

Anyone want to hazard a guess as to what is causing this?

(BTW, if this type of thing doesn't bother you too much, then otherwise
the STe is a pretty good machine to buy, especially if you can get a 2
Meg machine for 450 GBP!)

Good idea. In fact, MiNT provides something like this -- if you call the BIOS, XBIOS, or GEMDOS with function code -1, you get back the address of the appropriate function table. Changing this table lets you patch into system calls.

> Why didn't anyone ever do this before?
>
See above; although MiNT is perhaps overkill if you only want to be able to hook into system calls easily, and don't care about multitasking, IPC, etc. If you do decide to write your AUTO folder program, you might want to consider using the same scheme (i.e. gemdos(-1) gets the address of the GEMDOS function table).

The other problem is that no one can be sure that the AUTO folder patch is available on every machine; hence, the constant re-invention of the wheel.

From: ekrimen@csuchico.edu
Message-ID: <1990Aug31.022711.21085@ecst.csuchico.edu>
Source record: 50320

- My STe does this 'phantom typing' thing a lot. It sometimes
- appears as if the escape key is being help down and other times it's
- the left mouse button. I've noticed that this often happens after
- moving the vertical slider bar of a window on the desktop. I've
- never tried to figure out exactly what causes this and I can never
- make it happen (with frantic mouse movement etc.) on demand.

I've seen this, or a similar problem, happen many times on my machine. Sometimes, my keyboard locks up. Sometimes it locks up with the keyclick ringing continously. Therefore, I just warm-boot. This is a temporary STe I have, that doesn't work with hard drives. The one I had before this, worked with hard drives, but the keyboard stopped working after a week. I don't remember ever having this problem though with the first one. I should be getting my new STe any day now (should have been a couple of days ago! UPS!!!) and if it persists, I'll mention it.

- I don't know if it's caused entirely by the STe or by software that
- I use (eg. mouse accelerator etc.) but it DOES HAPPEN on the STe.

I had thought it was STalker doing it, but I don't know. Desk accessories that multitask sometimes start the 'Esc key sequence' when you move the mouse while the da's are operating, like with Mystic and STalker. I'm sure someone here knows what causes this, however.

- Anyone want to hazard a guess as to what is causing this?
-
- (BTW, if this type of thing doesn't bother you too much, then
- otherwise the STe is a pretty good machine to buy, especially if you
- can get a 2 Meg machine for 450 GBP!)

I wholeheartedly agree!

But that's what the cookie jar is for. A program that wants to patch
the jump table can test to see if the patch is there already. If not,
it can install it itself or else install its own trap handler the old
way.

But if you need to be able to install it yourself, you're not really saving
anything :-(. I suppose you could check the cookie jar and if the 'TRAP'
or 'MiNT' cookie is not there, print a message telling your user to get
the appropriate software. Seems a bit ugly; unless the trap handler provides
some really nice services (or you need some MiNT specific facilities).

If you've got to have the code in your program for installing the trap
handler yourself, you've had to re-invent the wheel again.

The BIOS and XBIOS routines are already somewhat re-entrant, and can be made more so by providing a bigger BIOS stack. GEMDOS is inherently non-reentrant. The safest strategy is probably just to set a flag in the interrupt routine, and then have the user code check the flag every so often and take the appropriate action.

189. How do I connect an Amiga monitor to an ST?

Newsgroup: comp.sys.atari.st.tech
Date: 1990-08-31 21:34:44 UTC
From: timcc@csv.viccol.edu.au
Message-ID: <6377.26de91a5@csv.viccol.edu.au>
Source record: 50327

I remember someone posted instructions for connecting an Amiga monitor to an ST last year. I can't find the posting in my archives, so is there anyone out there who has a copy, or knows what the setup is?

190. Adding another HD

Newsgroup: comp.sys.atari.st.tech
Date: 1990-09-01 17:48:36 UTC
From: ekrimen@csuchico.edu
Message-ID: <1990Sep01.174836.8094@ecst.csuchico.edu>
Source record: 50330

I may have an opportunity to get a used 20meg hard drive cheaply.
I'd like to add it to my current system consisting of an ICD case with
host adapter and an ST157N-1. I'm pretty sure that the drive I'm
getting will be MFM or RLL. I don't have an OMTI or Adaptec
controller (which cost around $100, right?), so would it be possible
to connect it to the SCSI controller already on the 157N? Can't the
embedded controllers control two drives? I know I'd have to change
some DIP swtiches or something so the host adapter can recognize the
second drive. Is there anything I'd need? Thanks for the help.

191. Adding drive Part II

Newsgroup: comp.sys.atari.st.tech
Date: 1990-09-01 20:14:05 UTC
From: ekrimen@csuchico.edu
Message-ID: <1990Sep01.201405.8709@ecst.csuchico.edu>
Source record: 50331

Remember I asked about adding a drive to my current hard drive system. The drives I have to choose from are as follows:

Seagate ST255, 20megs, MFM, 1 year old, no bad sectors
Miniscribe HH225, 20megs, MFM, 3 years old, 1 bad sector

I would probably go with the Seagate. Is this drive worth investing $100 for? I already have an ST157N-1, and I'm afraid I'd have to shell out another $100 for an Adaptec or OMTI controller to get the drive to work with my ICD host. Is there anyway I can connect the ST225 to the embedded controller on the ST157N? I am assuming that it would be a direct connect if it was possible, and I wouldn't have to do any soldering or tweaking of any kind.

All information, stories about working with these drives, or adding another mech to an existing system would be greatly appreciated. Thanks for the help!

192. Re: Malloc() and desk accessories

Newsgroup: comp.sys.atari.st.tech

From: gt1448b@prism.gatech.EDU
Message-ID: <13263@hydra.gatech.EDU>
Source record: 50332

In a previous post on this subject, it was mentioned that making a call to v_opnvwk() did a Malloc, thus problems can result from DA's which call it. In ACSKEL.C, a v_opnvwk() is called when the DA is opened, and a v_clsvwk() is called when a DA is closed. Therfore, this example of a desk accessory is not coded "correctly". What is the correct way to call v_opnvwk()? Should it be done before the event loop and v_clsvwk() never called?

193. Floating Pt. Math with a 68881 not always faster

Newsgroup: comp.sys.atari.st.tech
Date: 1990-09-01 23:00:09 UTC
From: moses@hao.ucar.edu
Message-ID: <8379@ncar.ucar.edu>
Source record: 50333

I have recently installed a math copressor into my Mega system
and have now linked my code with libraries supporting a 68881 chip
in a ST.
While more complex math functions, such as transcendentals and
square root really show a speed increase, adding or multiplying two
floating point numbers do not show any speed increase over just
doing it with the 68000 chip. Matter of fact some of my functions
that do repetitive mulitply and additions with floats (without more
complex functions) are significantly slower when using the math
copressor.

Q- Can someone explain why?

My best guess is that the time the processor takes to transfer
the floating point numbers and also the time waiting for the math
copressor to be ready to receive makes the simpler math operations
slower than just doing them inside the 68000 chip. I am using the
Prospero math libraries that look once for the math chip so that one
must link for either a 68K chip with or without the math chip,
exclusively.

Message-ID: <1990Sep02.200943.14691@ecst.csuchico.edu>
Source record: 50335

For those of you interested in the answer to the question "Is it possible to connect a drive (MFM or RLL) to an embedded controller on a SCSI drive without adding some extra hardware?" the answer is no. You must get at least an MFM-to-SCSI controller which, one person told me, costs around $150. Or, from my experience, you need an Adaptec or OMTI controller to connect to the host adapter. Therefore, the cost, sans drive mech, would be around $100 for the Adaptec or OMTI controller.

If anyone knows anything different than this, please post it to the net because there are other people on here that are interested.

Ah, but there is a simple solution: you need a ATARI-to-SCART adaptor cable.
If you can't buy one at your local computer dealer, just buy normal SCART
cable (as used for VHS tape-to-tape copy) and an ATARI monitor connector.
I don't have the pin connections at hand at the moment, but I'm sure you
can look them up in the relevant technical literature.

Hope this helps,

Techno

gt1448b@prism.gatech.EDU (David P. Forrai) asks:

| What is the correct way to call v_opnvwk()? Should it be done before
| the event loop and v_clsvwk() never called?

The best way for desk accessories to handle opening virtual workstations is for them to use them in the same way they would use any other dynamically allocated resources. Open the workstation, do VDI calls, close the workstation. It isn't a good idea to suck up a virtual workstation slot which may never be used.

You're right, if that's what ACSKEL does, the behaviour in ACSKEL is incorrect.

The effects of dynamic DA Malloc() and v_opnvwk() calls only recently became apparent, when the GEMDOS internal memory management was improved for TT TOS. A side effect of the change he made was that the likelihood of a freed block getting reallocated soon after being freed became much greater. In previous TOS versions, it takes longer for freed blocks to be reallocated. Because of this, you are less likely to see problems arise when DA's don't get a chance to clean up after themselves. It is still and always will be A Bad Idea to mess with memory you don't own, and that's effectively what DA's do if they dynamically Malloc memory (either directly or indirectly).

To end on a happy note--the problem of DA's not getting a chance to free up their resources before having them yanked out from under them is FIXED in the AES version 3.0. The AES now actually waits until all desk accessories are back in an event wait before allowing an appl_exit caller to terminate. The new Control Panel (XCONTROL) takes advantage of this fact, and dynamically allocates memory to load Control Panel Extensions if it sees that it's on a TT. This should also be a great boon to desk accessory text editors and the like.

Maybe the routines of Prospero are not very fast, or they are only
single precision.

The 68881 uses 80 bits, generally double precision takes 4 times longer
then single precision.
In Turbo C, which has the fastest floating point library available to my
knowledge, 80 bits take 3 times as long as the 68881 does. So
if there were single pricision routines they would be a bit faster
then the 68881.

Source record: 50243

Some years ago a wrote my own set of floating point routines.
Then a little later I got the chance to test a 68881.
My findings were that single precision addition was not any faster
on the 68881, but all others were. And those were very good
floating point routines. On the whole however the speed increase
with the floating point chip wasn't realy spectacular.
Over the original Absoft library I measured on one of my calculational
programs a factor 4 with the 68881 (and a factor 2 with the home made
library).
Most of the time is lost in the transmission and the negotiations
with the chip. This won't be the case so much on the TT as it has a
directer channel.
A compiler that can use the floating point registers will also make
an enormous difference, because then nearly all transmission delays
are reduced by a factor 4 to 5.

If you find that multiplication is faster without the chip you have
either an incredibly fast FP library, or an inefficient link to the
68881.

If that 'cheap' Drive is an SCSI Drive, just connect it to the SCSI Bus
at your ICD Hostadapter, but if that Drive is a MFM/RLL Drive, you should
get an OMTI or Adaptec 40X0 or the Controlerpart from a SH205/204 or the
Megafile 30/60, but you can't connect a MFM(ST506 Bus) to the SCSI Bus,
you will probably damage your Drive and Hostadapter if you do it, so be
careful.....

The above messages and some others point to a solution to
the question: why are simpler F.P. math functions slower with the
68881 than with the 68000?

Ken and Pete,

Yes the Prospero libraries are not highly optimized as compared
to Turbo C or Megamax C but they are a solid group of functions supported
by a good working environment. However, the Prospero 68881 LIBS, I
would wager, are faster than Megamax C's libraries for two reasons:
1) Prospero's looks once for the 68881 at program bootup for the math
chip while Laser C looks for it everytime it wants to do F.P. math,
2) Prospero comes with two 68881 libraries, the second has no error
checking and that eliminates some overhead (though you better know
what the ranges of the solutions will be).
The solution is that I was comparing single precision (32 bit)
F.P. math being done by the 68000 to 80 bit math by the math copressor.
Complex F.P. functions, such as Tangent(x), are always faster when
done by the 68881 math copressor, but simple functions such as add,
subtract and multiply are <slower> because of the time taken :
```

1) waiting for the 68881 chip to be ready to receive, 2) moving 32 bits to the math chip, 3) the math chip converting the the 32 bit floats to 80 bit floats, 4) returning the solution back to the 68000. I am doing my single precision F.P. math in Fortran subroutines and linking them into my Pro-C. Double precision F.P. math, such as done by C, I would agree, is probably always slower than the math by the 68881.
Having looked at the Alcyon 68881 assembly source code, there does not seem to be much one can do to further optimize the F.P. routines. Prospero's are probably based on Alcyons. The TT's copressor will probably run circles around any single precision done by a 68xxx CPUs (I hope).

207. using evnt_timer() with GCC 1.37.1

Newsgroup: comp.sys.atari.st.tech
Date: 1990-09-03 18:27:11 UTC
From: rcb@netcom.UUCP
Message-ID: <13154@netcom.UUCP>
Source record: 50247

I have just ported my first program which uses Turbo C's graphics to GEM and the Atari ST. Everything works except for when I call evnt_timer().

I have checked out 3 different sources on the parameter usage and they all have a different story. Abacus' GEM Programmer's Reference says that evnt_timer() takes two 32-bit parameters, which make up a 64-bit millisecond delay (the first parameter is the low-order 32 bits ...). Tim Oren's Profession GEM series column 12 specifies that the millisecond delay is a 32-bit value passed as 2 16-bit parameters. The aesbind.h file that comes with GCC 1.37.1 says there is one 32-bit parameter. I have tried all of these and the result is always that my timer waits a lot longer than I would like (i.e. the machine seems to lock up). If I reverse the order of parameters (where there are 2 parameters, of course), there is no delay. Can anyone help?

>floating point numbers do not show any speed increase over just

Amazing! Of course, for '+' oder '-' there will be no much speed
increase (because of the data-transfer via supervisor-mode) , but for
'*' oder '/' you should expect at least a factor of about 2.

Perhaps the library is not so good??

Does anybody have any experience with PC DITTO II for the st???
A friend has bought this but cant make it work. Sorry but I only talked
to him for a minute and didnt get much of a description of the problem.
I Know a little about IBM harware but nothing of ATARI. Are there the same
concerns regarding interrupts, dma,etc.
Any pointers you can give would be appreciated.....

Thanks
G. James

In article <989@nikhefh.nikhef.nl> t68@nikhefh.nikhef.nl (Jos Vermaseren) writes:
>If you find that multiplication is faster without the chip you have
>either an incredibly fast FP library, or an inefficient link to the
>68881.

It's also worth noting that the 68882 can overlap execution of f.p.
instructions, assuming there aren't any operand dependencies. The
68040 (which doesn't implement the full '881/'882 instruction set,
but does do the "core" -- FMUL, FDIV, etc) also overlaps, and (since
it directly implements the instructions itself) doesn't incur any
of the coprocessor overhead of a '881/'882.

In other words, there's good reasons to not do floating-point in
software, even if you can shave a few clocks in a few instances
on your current hardware by doing so.

In general, anything 150ns or faster is OK for memory expansion in an ST.
The Intel 120ns DRAMS you're getting should work fine.

214. TOS 1.4 vs. old (1988) ICD HD utilities

Newsgroup: comp.sys.atari.st.tech
Date: 1990-09-04 18:31:41 UTC
From: pesch@pa.reuter.COM
Message-ID: <384@saxony.pa.reuter.COM>
Source record: 50254

Over the Labor Day week-end, I finally upgraded my trusty old 1040ST to TOS 1.4 (using the six-chip set). It's very nice---but only if I boot off a floppy and forget my hard disk!

My HD is built from an ICD host adapter kit, and has been happily booting off icdboot.sys (nee .prg) with the old TOS. ICD, over the phone, claim the problem must be the program that talks to the clock; I am skeptical, because the first thing I did when I noticed this was to make myself a floppy with *nothing* in the "auto" folder *except* icdboot.prg, and teach myself to hold down the shift and alt (or was it ctl and alt? I'm away from my machine and ICD instructions at the moment) at just the right moment when the floppy access light comes on.

I can tell it's booting off the floppy because the *only* console message is from icdboot (on the HD, I run a number of other things, like pinhead and foldr400 and copyfix---I mean, I *used* to run---but their startup messages do appear when crashing off the HD).

Whether I crash off the HD or off my stripped-down floppy, I get two bombs ---it looks like just when it's trying to give me a desktop (in either case, I always see all the expected boot-process console messages first).

I have not installed the Rainbow TOS patches, since they're sitting in an ARC file on my inaccessible hard disk...

Two questions, then:
(1) Is my problem unique? (I hate being unique this way).
(2) Assuming it isn't---what is the known fix? (subquestion: will I have to reinitialize the hard disk?)

Many thanks!

/Roland

- console messages first).

If you *are* using the old utilities, by all means GET THE NEW
UTILITIES!!! Now that that's off my chest, you may want to check
that ICDBOOT.SYS isn't corrupted. One way to check this is to GET
THE NEW UTILITIES!!! :^) Call their BBS and download them, call ICD
and have them send you a disk with them on it (~$10), or maybe I
could send them to you. (I know, I'm going to get flames, "ICD
copyright rules state, 'You may not distribute ICD utilities to
fellow ICD host adapter owners. We want as much money as we can
get!'")

216. Hardware-related csd failure

Newsgroup: comp.sys.atari.st.tech
Date: 1990-09-05 03:18:24 UTC
From: saj@chinet.chi.il.us
Message-ID: <1990Sep05.031824.4767@chinet.chi.il.us>
Source record: 50259

This has the feel of one of those problems that's going to take more brains to solve than are conveniently assembled in one place. Here goes:

Doing some development on my MEGA 4 (TOS 1.2, msh, minimal AUTO and accessory complement). I went to invoke the Mark Williams csd debugger (gem csd <program>). And the screen went blank. That never happened before. Some playing around showed that csd was, in fact, running, and controlling my program. But the source code listing, the help messages and the functioon key labels were either not on the screen or drawn white-on-white. The screen display of my program (what is it, F7?, F6? whatever..) was normal. Once I caught on, I was able to terminate my program and csd in the usual way.
Every test I've tried comes out normal. Other programs run just fine (although I don't have that many 'challenging' ones handy). A memory tester shows the right amount of memory and says it's good. Comparing csd and msh to the distribution disk gives a match. I restored all the system stuff from a backup just for jollies, and it changed nothing.
The reason I consider this a hardware problem is that when I switched the hard disk (ST296 on a BMS-200; configured as 4 15 Meg partitions and a 20 (which last is not used for this program nor for system files); Supra software) to a 1040 ST, csd worked properly.
I'm resigned to needing repairs. But I'd rather get them locally than have to swap my MEGA with Atari (time and money advantages, both). The problem with that is that this problem seems a bit too subtle for the service guy to get a grip on. Anyone out there have a bright idea what I should tell him?

Steve J.

217. How to connect a Priam V185A ??

Hi Netlandians !

I am able to get a Priam V185a Harddisk !
Does anyone know how to connect it to my Atari St ?
Which bus does it have ? ST-506 or SCSI or ??
If anyone can help me he will be welcome.

Greetings

Marvin

218. Upgrading Megafile 30

Newsgroup: comp.sys.atari.st.tech
Date: 1990-09-05 12:52:37 UTC
From: kentd@FtCollins.NCR.com
Message-ID: <KENTD.90Sep5135237@zappa.FtCollins.NCR.com>
Source record: 50256

I think someone recently posted a question along these lines but I
haven't noticed any replies, so I'll post my question:

I have a Megafile 30 HD and was wondering if it's possible to just swap
in a new drive for the existing mech.? I've got a feeling it should be
pretty simple... the software side of things would probably provide the
most trouble.

Looking inside the case reveals an ST238R drive mech. (RLL , 30M, 65ms)
It's connected to the adapter via two ribbon cables. I was thinking
of replacing it with an ST277R (RLL, 65M, 28ms)....

If anyone has done this or has any suggestions, ideas, hints, please let
me know.

Also, as a side note, I couldn't discern a seperate controller...
I thought the flow was supposed to go:

DMA -> SCSI Adapter -> SCSI to RLL controller

Is this the case the Megafile 30?

Any info would be much appreciated...

Disclaimer: I have BMS, and like BMS.

The boot process that ICD and Supra use is fairly tricky. They search the
root directory themselves and need to fake out the TOS ROM boot sequence.

These can be done without being TOS # dependent but it easier to do it wrong.
There has been much chatter here and in ...minix... with the result that
ICD is always puttingh out a 'fix'. I think that they may be cheating.

Try to run a utility from disk that will turn off the autoboot.

p.s.

Way back, Dave Small had a neat program in START that would bypass the booting
of an adled hard disk. It does cheat -- jumps into ROMS. The address needs
to be changed for TOS1.4 but it the only sure fire way to get control when
1) the boot image is sick or 2) .acc progs are bombing. It saved my life
(i.s. hard disk) several times.

Message-ID: <9462@ubc-cs.UUCP>
Source record: 50263
Cross-posted to: comp.sys.atari.st.tech,comp.sys.handhelds

Could some one please send me a configuration for the rs232 cable from
a portfolio to a st. The manual supplied with the serial interface for the
portfolio does not have a set up for the atari st. This is a little weird
considering what other machines atari makes. :-)

Also, if any atari st owners have successfully established communications with
their portfolio I would like to hear from them, in case I have some
questions.

The portfolio is a nice little toy, (Ooops, I probably just offended some
person who thinks it is not proper to talk about non-st stuff here) there
are a couple of things which are disappointing, 1 no decent calculator, 2
no programing language. O well.

As expected, the information that my machine's screen goes blank when I run Mark Williams's csd doesn't help the shop guy at my local dealer. I've found a much smaller and simpler program that displays the same symptom: MELT.ACC (you know, the screen sags in the middle and melts off the monitor). If I can get the source code to it, the odds are very good that it'll be possible to see just where my machine screws up. Any availability? Please?

His problem is surely that the clip is not on properly.
It needs to be *VERY* *VERY* tight - a sharp tug should not pull it off.
The pins need to be VERY VERY DEAD LEVEL with each other. Use a ruler.
Squint along the pins. A single pin out of alignment will cause the thing
to fail.

I was in your friend's situation for some time. I would not believe that this
was the problem. But it is. I have never seen Ditto-2 fail for another reason.

Lately, my 520ST has been havng problems. The screen begins to show garbage. It seems like the memory is being corrupted because the mouse will be going and the garbage is still on the screen. What happens is the pixels in the even columns (of a mono screen) get garbled. The end result is a screen of clean columns and dirty columns. The dirty columns also show bands of white and black. I suspect this is a memory problem because the garbage shows up on byte boundaries. Could it be that one bank of SIMMs is not being refreshed properly?

This is my system:
520ST circa 1986
JRI RAM+ with 2 meg simm (total 2.5 meg)
2 external floppies
1 hard drive w/ ICD controller
1 modem, 1 printer
Spectre GCR

Auto:
Fatspeed
Pinhead
Maccel2
ICDTime (in this order)

Daccs:
Quick ST 1.26
Control Panel/Install Printer

What should I do!!!!

Well, not practical, not nice, not useful, but definitely possible. You (the intrepid programmer) write a new malloc which returns pointers to pointers: aka handles. The pointer returned is a pointer into a table; the table is made up of pointers to memory fragments. Toss in some swapping algorithms and you have a private VM system which can defrag memory and do other neat stuff. If you are the of the TOS-sux-so-I'll-install-my-own-OS types, this would not be unfathomable.

In article <8387@ncar.ucar.edu> moses@hao.ucar.edu (Julie Moses) writes:
| Having looked at the Alcyon 68881 assembly source code, there
|does not seem to be much one can do to further optimize the F.P.
|routines. Prospero's are probably based on Alcyons. The TT's copressor
|will probably run circles around any single precision done by a 68xxx
|CPUs (I hope).

If you're looking for fast math, you could perhaps make use of representation of real numbers by integer quotients; this is a common technique when precision and/or range allow it (which is the case for a lot of real-life applications). Each real (or float if you want) is represented by a pair of integers (choose either longs or shorts), whose quotient is the real (approximately). Especially in cases where shorts can be used for the representation (low precision), and on a processor that prefers integers to floats this can boost up calculations dramatically.

Another way to possibly increase performance is to put often calculated function values in an array, e.g. for sin(x) calculate sin(i*pi/180) for i = 0..90. Intermediate values can be found - for example - by linear interpolation.

For an example of quotient calculation, you can take a look at the sources of the 3D demo program I wrote a while ago.

Cheers,

Leo.

Toss in some swapping algorithms and you have a private VM system which can defrag memory and do other neat stuff. If you are the of the TOS-sux-so-I'll-install-my-own-OS types, this would not be unfathomable.

No! You would still have to handle the case where someone actually tries to _access_ data that has been paged out (you mean you have to be able to read it back??). This entails first of all being able to recognize an interrupt caused by accessing memory that was paged out (this part might be possible) but after paging that data back in, you have to be able to continue from the interrupt as if nothing had ever happened. The fact that this is not a supported operation on the 68000 makes it unlikely that such a program could be written.

You are describing transparent virtual memory. There are other kinds,
and perhaps the original poster is willing to live with virtual memory
where he is required to explicitly ask for the memory, and release it
when he's done. The Mac does this, and Windows 286 does this.

233. evnt_multi() mouse button event behavior?

Newsgroup: comp.sys.atari.st.tech
Date: 1990-09-10 20:51:46 UTC
From: saj@chinet.chi.il.us
Message-ID: <1990Sep10.205146.8025@chinet.chi.il.us>
Source record: 50273

This keeps getting in my way, and I keep working around it. When exactly does a properly set-up evnt_multi() get mouse button events? The latest situation is that I'm waiting for (among other things) single button clicks over the part of the screen my application owns. When I open the control panel over my window, I can move the color selector buttons around to my heart's content without getting spurious messages. But when I try to drag the control panel window around on the screen, I get a mouse button event exactly as the mouse pointer leaves the original outline of the c.p.w. This doesn't match the documentation (as I read it). So what's really happening here? Is it TOS version dependent? And to what extent does someone care to explain the rest of the REAL behavior of this type of event?
Steve J.

234. Reading IBM PC 5 1/4 Disks (360k) on an ST

Newsgroup: comp.sys.atari.st.tech
Date: 1990-09-10 23:12:34 UTC
From: crichmon@digi.lonestar.org
Message-ID: <958@digi.lonestar.org>
Source record: 50274

I get source code on IBM PC 5 1/4 inch floppies (360 k) and
I need the capability to read these disks with my Atari ST.

I know that the Atari ST uses the same disk format as the IBM
PC. I saw a 5 1/4 inch disk drive in a magazine once that
was designed for use with PC Ditto. Does anyone know if that
will work with regular Atari ST disk reads and writes?

Can anyone send me some plans for converting an IBM PC disk
drive to work with the Atari ST? I can get a drive with power
supply for about $100, but I am sure some extra circuitry or
wiring will be necessary to make it work with the ST. Also,
I would need a plug that will fit the Atari ST floppy drive
port.

Thanks for any help that you can send me! I will post a summary
to the net if I receive some good information.

>
> If you are using just a plain-vanilla 68000 in your machine, this is
>completely impossible.

Anything's possible :-). It's true that the 68000 doesn't support demand paged virtual memory. (If you really must have it, you can always write an interpreter for a virtual machine; but this will be *slow*). However, swapping whole processes in and out of memory is possible, if the processes don't intercept any interrupt vectors and don't mess with memory they don't own. I plan on adding this feature to MiNT at some time (unless some intrepid programmer beats me to it -- the hooks are already there in the code). Done properly, swapping need not even be very slow; typically you'll only have one process running, with others sitting in Pexec() waiting for children to finish -- prime candidates for swapping.

237. CPMZ80 and TOS 1.4 - A Fix

Newsgroup: comp.sys.atari.st.tech
Date: 1990-09-11 04:13:08 UTC
From: os9paul@gkcl.ists.ca
Message-ID: <12318@ists.ists.ca>
Source record: 50275
Cross-posted to: comp.sys.atari.st.tech,comp.sys.atari.st

The CP/M emulator from Atari DOES work with TOS 1.4, but it does require a minor patch.

On the TOS disk, rename the file INIDSK.COM to INIDSK10.COM (it works with TOS 1.0 and TOS 1.2). Copy CPMDATA.DAT to CPMDATA.BAK just in case. Using your favorite disk editor, you must change one byte in CPMDATA.DAT. Locate cluster 19 (aka sector 38). This begins with the hex sequence 31 DA 03. At offset B8 the original byte is 08; change this to 00 and save the change. Or you may search the file for the sequence of bytes 7E FE 08 20 0C, and change the 08 to 00.

That's all there is to it. The file CPMDATA.COM actually contains the information for the TOS directory on the CP/M disk, the CP/M directory, the files INIDSK.COM and TOSCPM.COM. The byte that must be changed is actually in INIDSK.COM. If this byte is not changed, any attempt to initialize a freshly formatted disk will cause the dreaded "Disk is not empty" error.

Code fragment for techie types:

```
...
LD HL,#008B ;byte just after first filename.ext in directory
LD A,(HL) ;this byte is 00 with freshly formatted TOS 1.4 disk
CP #08 ;must have been 08 with older TOS versions, make 00!!
JR NZ,1C7 ;display "Disk is not empty"
...
```

ASSORTED NOTES:
The version of the CP/M emulator that I am using signs on as follows:

```
CP/M-Z80 Emulator Copyright (85) SoftDesign Munich
Release 9.4 Version 7 for ATARI TOS
```

I followed the directions in the READ.ME file to create a single-sided PSEUDO CP/M disk. I then formatted a double-sided (720K) disk under TOS, started the emulator by double-clicking on CPMZ80.TOS, and inserted the SS CP/M disk when requested. Then I used the command 'inidsk b:' to initialize the 720K disk. I used TOSCPM.COM to copy all the CP/M files from the TOS disk to the 720K CP/M disk.

Two drives are required to set the emulator up, but after that it will work just fine with one drive. (Note that scopy may be used to do single drive copys from one CP/M disk to another CP/M disk.) If you only have one floppy and a hard drive it is still possible to create your CP/M disk. Make a CPM folder on the C: partition of the hard drive and copy all the CP/M files into it. Open the CPM folder so that it is

active. Now open A: and run CPMZ80.TOS from it. Insert your CP/M disk into A: when prompted. Use the command:

toscpm c:filename.ext filename.ext

to copy each file to the CP/M disk. Do not use a backslash after the c: and all will work well.

BTW, when you run MAKE_ME.TOS and it prompts "Press any key...", it actually means "Press any key provided it is marked 'Return'". :-)

Is it possible to connect more than one SCSI device to the SH204 host adapter?

I have tried the following, but have not been able to get the computer to recognize more than one drive at a time:

Setup one:

SH204-----Seagate 251N-----Adaptec4000A=====Seagate 251 (LUN 0)

Setup two:

SH204-----Seagate 251N-----Seagate 225N

Perhaps I am mistaken about some aspect of how SCSI works, but I thought that I should be able to use setup one and have the 251N as DEV 0, LUN 0 and the Adaptec/251 as DEV 1, LUN 0.

Has anyone been able to connect more than one SCSI device or intermix imbedded drives with Adaptec controllers? Is this possible with the SH204 host adapter or must I buy a different flavor? Any ideas about wht I may be doing wrong?

TECH INFO: The SH204 host adapter has the ADE PAL installed. Hard drive software is Supra 2.72; TOS is 1.4.

240. 640x400 on an SC1224

Newsgroup: comp.sys.atari.st.tech
Date: 1990-09-11 05:30:48 UTC
From: ekrimen@csuchico.edu
Message-ID: <1990Sep11.053048.29756@ecst.csuchico.edu>
Source record: 50277

A person on Fidonet mentioned in a reply to a post that the SC1224 is capable of handling 640x400 resolution. He also said that he thought it could handle 16.7 million colors, but that he wasn't sure.

Forgetting about the 16.7 mil colors for now :^) , is it really possible to get 640x400 on an SC1224? Would it be difficult to read because of flicker or anything like that? If not, it sure would be nice to get that kind of res with even 4 colors. The TT supposedly has a 640x400 mode, but that requires a multisync, doesn't it? I'm not a programmer, but I've heard that GEM is capable of detecting several resolutions and the programs that follow the rules should adjust accordingly, like on the Moniterm. If the 640x400 is readable on a SC1224 without any ill side effects, couldn't a patch be made like BigScreen or MonSTEr? If so, could someone please write one. :^) I'd buy it in an instant.

it is even worse, suppose the data that is paged in is executable code
it is unlikely that you can put the code segment at exectly the same place
as it was before, so in the worse possible case you have to relocate the
complete program. And what about those parts of TOS,AES,VDI, etc that expect
certain data at specific adresses.

So even if you have the hardware to support paging, you still have to hack the
complete TOS to support it too.

> Is it possible to connect more than one SCSI device to the SH204 host adapter?

No. But, you should be able to use TWO SH204 host adapters (make me an offer for my old one). The DIP switches on the HA should be your clue; the Atari HA is useless for multiple devices. Note also that the Atari HDX software is useless for anything but Dev0/LUN0.

I have 3 HDs connected to two Adaptec 4000A controllers to an ICD HA, and run ICD software. With no problems...

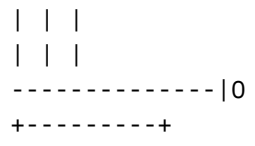
Yes! No, buy another HA. Yes, you are making an invalid assumption about "Power without the Price".
>
> TECH INFO: The SH204 host adapter has the ADE PAL installed. Hard drive
> software is Supra 2.72; TOS is 1.4.

TECH TIP: If you want to dedicate one drive for testing and one for production work, try this trick:

Cont-0 DPDT-switch Cont-1

```
+---------+
--------------|O O O|-------------
```



Connect the wires to the address selection jumper pins on the controller (the ones which cause the controller to respond to Dev1 when a jumper is installed). Then, when the switch shorts out the pins on Cont-1, all is normal. Flipping the switch causes both controllers to swap identities (0>1 and 1>0). Works great and allows trying different boot programs without risking the need to go back to diskette if a new boot program doesn't work; just flip the switch and reboot from the other controller...

This is a pretty common problem with upgrades and has to do with ringing on the CAS lines to the extended ram board, a couple of 33pf capacitors on the end of the two CAS lines on the expansion board will probably work wonders.

Cheers!greg

248. STe info

Newsgroup: comp.sys.atari.st.tech
Date: 1990-09-12 00:33:25 UTC
From: ekrimen@csuchico.edu
Message-ID: <1990Sep12.003325.4451@ecst.csuchico.edu>
Source record: 50288

I just talked with Dave Cagle at Atari Tech Support. I asked him a few questions about my STe. The general concensus seems to be that if it doesn't hurt the hardware, don't worry about it.

I asked him about TOS 1.62 and he said he has no ETA on when or if it will arrive. Someone sent me some e-mail about a month ago telling me that he got a replacement STe from Canada and it had 1.62 in it. From what I've heard, you can tell if it's 1.62 because the ROMs have "Release 2" on them. Maybe I should have asked him about "Release 2 of 1.6" instead of 1.62. Kinda like the old story that there's only one mouse made by Atari, the STM1, although they are, or used to be, of different quality and made in different countries. In fact, all the STe's I've seen have the same kind of mouse, a good one I might add, and there's no "Made in...." on it.

I asked him about the delay for hard drives. I heard on here (should I lay it on Allan Pratt? :^) that there's a 90-second delay when you turn on the STe to allow the hard drive to come up to speed. I asked Dave about it and he said that only the Stacy's do this. My first STe paused, but now that I realize it, the one I have now doesn't. Weird.

Finally, the floppy light doesn't go off after the hard drive has booted. I thought that TOS 1.2, 1.4, and 1.6 was supposed to turn it off. I think he said that some do and some don't. As long as it doesn't hurt any hardware, don't worry about it, he added.

You can get JRI's SIMM module upgrade. I think it's around $140
retail. With an extra $40 or so, you can have the 4096-color
palette. If you want a number for a place to get the board, leave me
e-mail.

BTW, where'd you buy your SIMMs?

250. GDOS fonts without GDOS

251. Re: Upgrading Megafile 30

Newsgroup: comp.sys.atari.st.tech
Date: 1990-09-12 15:56:48 UTC
From: wayneh@ux5.lbl.gov
Message-ID: <6911@dog.ee.lbl.gov>
Source record: 50191

If this isn't too late ...

I upgraded my Megafile 20 from a ST225 to a ST251. This is MFM, but I assume the Megafile 30 is just an RLL version. It worked fine.

The board contains the adapter and the controller (Adaptec 4000 in my case).

Wayne

252. Sozobon asm

Newsgroup: comp.sys.atari.st.tech
Date: 1990-09-12 16:35:25 UTC
From: randyh@hpsad.HP.COM
Message-ID: <18420003@hpsad.HP.COM>
Source record: 50192

I need some help with a problem. The following source fragment is for MEGAMAX C. I'm trying to compile it with Sozobon and it barfs on this asm code. Could some kind soul show me how to get Sozobon to accept this code. The var 'program' is a pointer to char.

thanks alot, Randy

```
------------------------------------------------------------------------
asm {
movem.l A6-A4,-(A7)
move.l program,-(A7)
jsr 0x32(program)
move.l (A7),program
jsr 0x88(program)
move.l (A7)+,program
movem.l (A7)+,A4-A6
}
------------------------------------------------------------------------
```

ekrimen@csuchico.edu (Ed Krimen) writes:

>BTW, where'd you buy your SIMMs?

ELKCO Corporation
800-24-ELKCO MC, VISA
1 meg SIMMs $49

I ordered SIMMs from these guys. The $49 is for 80ns, $50 for 70ns ones.
This was the cheapest price I found for anything less than (or equal to)
120ns. The SIMMs arrived the next day! There was a 3% credit card charge
:(and a $6 shipping charge but it was still the cheapest price I found.

My STe still hasn't arrived. I will post if I have any problems with
the chips once I get the STe and can test them.

254. Does TOS convert CR to CR/LF on printing?

Newsgroup: comp.sys.atari.st.tech
Date: 1990-09-12 23:36:32 UTC
From: jimh@ultra.com
Message-ID: <1990Sep12.233632.3227@ultra.com>
Source record: 50194

I wanted to print some overstrike graphics on my Epson-compatible.
I believe I have all the dip-switches set so that isolated CR's
do not linefeed. Yet I can't get this to print correctly - all
CR's appear as CR/LF.

I know that TOS-written records end in CR/LF, but these ASCII files
were not generated by TOS.

I'm not sure but I think TOS is changing the CR to CR/LF's on the
way to the printer. Before I go banging my head any further:

Is this correct? If so, is there a way to disable it?
If TOS is at 'fault' would some kind soul explain the conditions
under which this transformation occurs in general and a bit
of rationalization on why?
Thanks,

>correct in assuming that the mouse port supplies +5v to the mouse? That is
>the pin I am concerned with (although I need to know the others too!!).
>Thanks!!

Ok, here it is. The diagram is from the external port view

```
-------------------------
\ 1 2 3 4 5 /
\ /
\ 6 7 8 9 /
------------------
```

1 - Up/XB
2 - Down/XA
3 - Left/YA
4 - Right/YB
5 - Not connected
6 - Fire/Left button
7 - +5vdc
8 - Ground
0 - Joy1 fire/Right button

Note, that the mouse port is the same as the joystick port 1.

This is taken from the ST owners manual, page 88 on my copy.

In my experience Sozobon's asm will only accept lowercased symbols
for register names. Remember that it is not a full assembler
but targeted to assembling output from the compiler. Why this should
prevent it from understanding either a3 or A3 I don't know.

Btw, I've come across a bug in asm which may be fixed by now. It
concerns the btst instruction which compiles into 4 bytes when it
should be 6 (or possibly the other way around, my memory is a bit dim
on this). Anyway, if anyone knows for certain how to obtain fresher
code or a patch, I'd appreciate an email to this effect.

Message-ID: <1990Sep13.134848.13057@chinet.chi.il.us>
Source record: 50197

I asked for help last week when my Mega stopped showing the program listing, button labels, etc in Mark Williams csd, and went blank when melt.acc was invoked. As predicted, the local service guy said 'bring it in when something less tricky goes wrong'. Well, that turned out to be the hardest part of the repair. D.E.G.A.S. wasn't working right, and he agreed that was a well behaved program. Turned out both MMU and DMA chips were failing. It's absolutely shocking that the machine worked almost normally with half its guts gone.

> jsr 0x88(program)
> move.l (A7)+,program
> movem.l (A7)+,A4-A6
> }
> ------------------------------------------------------------------------

I'm not sure what this fragment does, but....

Embedded assembly isn't a defined feature of the C language -- it's
implementation-dependent. Sozobon was written to be compatible with
Alcyon C, which uses this syntax:

asm("mnemonic arg1,arg2");

Sozobon & Alcyon also prepend an underscore to C identifiers to avoid
collisions with labels used in pure assembly modules. Thus your asm
fragment would look like this, assuming "program" is defined in your
C code as "char *program" or the equivalent:

asm("movem.l A6-A4,-(A7)");
asm("move.l program,-(A7)");
asm("jsr 0x32(_program)");
asm("move.l (A7),_program");
asm("jsr 0x88(_program)");
asm("move.l (A7)+,_program");
asm("movem.l (A7)+,A4-A6");

A7 also may be referred to as "sp" (for stack pointer).

Beware that some code prepared for Megamax/Laser C may contain
capitalized asm mnemonics, etc., that Sozobon won't like.
```

Another way to port this code would be to write the function in
assembly and include the .S file in the command line to CC.TTP.

Also, Tony's optimizer chokes on some weird assembly language, notably
anything having to do with Line A. Such modules have to be assembled
separately into .O files, then linked, as in:

cc -o test.tos test.c fubar.c linea.o

Source record: 50198

In the August issue of ST Informer page 7 there is an add for
the new Simms board $119.95US for the board itself. Therefore
with this board you can plug in your existing simms and upgrade
to 2.5 to 4meg etc. It fits neatly between the power supply and the
internal disk drive and uses power from your disk drive. For those
without spare simm board they can be bought cheaply in Toronto if
anyone wants some store names just send me mail. The number to
call for this simm board is Trinformation call collect (818)363-1004.
If I were upgrading my memory I would only use Simms now that they
are available as this board is eady to install so any bozo can now
upgrade his ST and plug in Simm boards.

The send-a-character-to-a-printer part of TOS doesn't change CR to CRLF. However, the Desktop might: if you double-click the file, and say "Print" (rather than "Show" or "Cancel"), you might be seeing that. If you're running a program to send the file to the printer, you should blame that program. (The Desktop is just a program in this sense, which is why you should blame *it* if that's what you're using.)

I have a few monitor questions:

1. I recently purchased a mono monitor, and I would like to know the easiest way to build a switch to switch between it and my color monitor. (On a side note, I heard that Calamus could support two monitors. Is this true, if so, how does it work.)

2. WHat are the pinouts of the high density 15 pin VGA monitor plug? And the 9 pin IBM monitor plug. (I would like to be able to plug my ST into me friends IBM monitors, if only to do color stuff. Also, our school has a big projection TV for the IBMs that I would really like to show my ST on)

Thanks for the info....

If your assumption were true, TOS were not able to print
bitmap graphics ! But You and I know TOS was able to do that !
So the only conclusion is TOS doesnot add/convert something.
So you have to reconsider your previous paragraph

> I believe I have all the dip-switches set so that isolated CR's
> do not linefeed. Yet I can't get this to print correctly - all
> CR's appear as CR/LF.

Do you really can trust your files?
Did you write a simple test program for that ?
(eg. printf("------\r!!!!!!\n"))

I had the same problem with including asm-files inC-source-text.
It works, if you include evry single assembler line in
asm (" assembler-code ") ;

don't ask me why including a packet of lines doesn't work.
i also hope the authors of sozobon will change this.
i wrote a programm which converts a asm-source to an acceptable
format for sozobon.( it reads a line from an input-file, and outputs
Print #1; " asm ("; chr$(asc(")); line$; chr$(asc("));") ;"
its a terrible basic-schotter, but i hope you see what i mean....

From: rick@jpusa1.UUCP
Message-ID: <1894@jpusa1.UUCP>
Source record: 50207

I've just sold my 386 system and picked up an old
Mega 2 and have tried to connect my Nec 3D monitor to it via
diagrams and a few suggestions. Right now I have something
that kind of works - The lines are connected thru 32 ohm resistors
on the color and sync signals, which works, but there's a shadow
on the text and a bright border on right edges that makes everything
look rather fuzzy and is a strain on the eyeballs... Almost like
the cable isn't sheilded properly, tho I know it is.
Anyone have any ideas? Could the signals be crossing over
in the cable? Do I need a lower capacitance cable? Higher resistors?
The signal is at about .6 volts now, if I go lower it gets pretty
dim on the screen...
Thanks for any suggestions !
Also - has anyone used the Omni box with the Nec 3d? Does
it work? Maybe that's the easy way out of this...

I have written one article on the Simm board upgrade so I better
add what else it offers besides memory expansion. First off JRI
Technologies is offering a Simms Upgrade Board for $119.95 US. through
TriInformation P.O. Box 5027, West Hills CA. USA. Call collect (818)
363-1004. This is the best and easiest board to upgrade memory in your
existing ST. Not only is it easy to buy Simm boards in Toronto etc but
the upgrade offers an additional enhancement I forget to mention in the
last article for $30 dollars more you can ask them to send an extra
video shifter chip that makes your ST have 4096 colours compatable.
You dont need this chip but its nice to have the extra colour display.

I solved the problem. I had been using Moshe Braner's 'more.ttp'
patched into the desktop.inf for so long that I forgot about the
desktop 'Show/Print..'.

When I removed the more.ttp application line from desktop.inf
and used the desktop print feature, the file listed
correctly with overstrikes.

On further investigation with some popular shells, I used
BARREL (also from Moshe - gee, that guy writes some pretty useful
stuff, whatever happened to him?) to capture the print output
to a file and saw that all these shells had somewhere converted the
CR to CRLF. Perhaps there's something in the Atari Development
Libraries doing it? (assuming these shells were developed from that).

If I ever get the time for trivia I'll check to see if Laser C
or GNU CC have this property and report back.

Thanks, to all those who e-mailed me with suggestions.

270. Moniterm monitors

Newsgroup: comp.sys.atari.st.tech
Date: 1990-09-14 20:15:50 UTC
From: 7103_2622@uwovax.uwo.ca
Message-ID: <6978.26f10236@uwovax.uwo.ca>
Source record: 50210

I am told that one cannot write directly on the screen memory of
a Moniterm (or similar large screen monitor). Do all of the line A
calls work OK with them? In particular, are bitblts to and from
screen memory feasible? I have a port of mgr (the Bellcore window
manager) that I'm finishing up, and I'd like to make sure that it
works on large screen monitors. Unfortunately, I don't have one :-(.
So any information would be appreciated...

I have heard some interesting rumors about the TT30. Is there such a product and if so just what is it (specs please).

I once owned an 1040ST and sold it to purchase a 386 system; but would like to move back into the Atari arena if there was a suitable machine.

Please e-mail the information as I have no other reason to read this group...

thanks in advance & no slight intended in above sentence frag. I always thought that the 1040 was an good machine.

Jeff Watkins

That's a feasible thing to do, but if you have an assembler that will compile it's code into *.O files, you can do it too. I found that all labels in assembly code which are required by the other *.O code written in C should begin with an underscore '_' (otherwise C compiler gives a message such as "symbol(s) missing: (whatever)"... I've done such things as described above for my bro when he couldn't get some stuff accomplished in C and needed me to write it in assembly... Worked every time.

- Is there a good program for restoring deleted files from a hard
- disk (with TOS1.4)? I have tried some version of Disk Doctor, but
- although it found the missing files, it did not appear to restore
- them.
-
- Thes files are not on the top level.
```

As long as you don't write to the drive after you've deleted the file, you should be able to recover it, also as long as it was only one file. Multiple files are more difficult, if possible. With Disk Doctor, you can choose the directory you want to recover the file from, as well as the root directory.

>I have heard some interesting rumors about the TT30. Is there such a product
>and if so just what is it (specs please).

Yes, there is such a *machine*. In the US, it is not yet a *product*. It is
already available as a product in Europe. It seems that the FCC is (once again)
to blame for the unavailability here.

It's going to be released with a CPU running at 32 MHz. Other folks can
probably provide more details...

I played with a couple while visiting the Glendale Atari Fair. The cases
look a little silly, but the machines seemed real enough, and fast.

>that I should be able to use setup one and have the 251N as DEV 0, LUN 0
>and the Adaptec/251 as DEV 1, LUN 0.

As far as I know from previous inspections, the SH204 holds DEV 0
selected all the time and never ever releases this selection until
power is switched off. This means that the SH204 host adapter is not
capable of selecting any other SCSI drive than DEV 0. At least, this
is what I have been told. You can, however, put a second MFM drive
of the ST506 type into your SH204 by connecting it to the Adaptec
controller. Using special software (i.e our software 8-) you can
then use the two drives. I don't know if the Supra software supports
two LUNs on a SCSI controller, too.

278. Re: Sozobon asm

Newsgroup: comp.sys.atari.st.tech
Date: 1990-09-17 15:00:11 UTC
From: randyh@hpsad.HP.COM
Message-ID: <18420004@hpsad.HP.COM>
Source record: 50218

Hi all,

First I would like to thank everyone who made suggestions via e-mail or replied to this note. I got the code to compile :-) , however, it doesn't do what I had hoped. (more about that later)

In order for it to compile I re-wrote the code as below. The other change I had to make was to the variable "program". It was originally declared a register char *program. When I compiled the code with the -S option and then looked at the source file I couldn't find _program anywhere accept in the asm fragment. After declaring program as a global above main() the code would compile because it now had a reference for _program. I don't know if everyone followed that, but I had a great time figuring it out. This is what the fragment now looks like.

```
asm("movem.l a4-a6,-(sp)");
asm("move.l _program,-(sp)");
asm("jsr $32+(_program)");
asm("move.l (sp),_program");
asm("jsr $88+(_program)");
asm("move.l (sp)+,_program");
asm("movem.l (sp)+,a4-a6");
```

This code is part of a program that makes use of routines in stspeech.tos to produce speech from text while bypassing the prompts of stspeech.tos. I have a program called speech.tos that I thought was the same thing as stspeech.tos but apparently is not. If anyone has stspeech.tos or has written a program that interfaces to the speech routines of speech.tos please let me know. I would like to write some programs for my chidren that incorporate speech.

Thanks alot,
Randy randyh@hpsadpk

>So any information would be appreciated...

Eric, Moniterm memory, or the memory of any other large screen Monitor is
just RAM that you read and write just like any RAM. For example, Quick ST
doesn't care where the screen is. On a Moniterm monitor, it starts at $c00000
while on a normal,say, 4096STE, it starts at $3f8000. A write to one or the
other will produce the same results. The only thing I can't tell you for
certain is whether you can access it in user mode. I always pop into supervisor
mode just in case.

The next best thing to a Moniterm monitor is a Moniterm monitor emulator, such
as MonSTEr (available with Quick ST 2.2). It allows your mono monitor to
emulate a 1280x960 monitor, and your color monitor to emalate 1280x480. I have
a new version about to be released that also emulates the ISAC monitor (
16 colors, 1024x768). If you run MonSTEr on an STE, the emulation is in real
time, otherwise it is at about 80% of full speed.

The reason you couldn't get a reference of _program was just what
you wrote: it was not a global variable. When I first looked at a simple
dissassembled *.O file, I was surprised to see that main() does a LINK
instruction in assembly. In other words, all variables declared in main()
are simply going to be temporary as they exist only on stack, and not in
real GEMDOS data area. I think in object files you can only get
references to procedures and global variables (although I MAY be wrong),
since local variables are just offsets on a stack...

I don't know if all of this made sense...

284. cartridge port.

Newsgroup: comp.sys.atari.st.tech
Date: 1990-09-19 13:45:13 UTC
From: q1rse@turing.newcastle.ac.uk
Message-ID: <1990Sep19.134513.25831@newcastle.ac.uk>
Source record: 50224

I asked this question a few months ago a got some useful replys, I
however am still stuck,

The plan for the cartridge port is this:
I wish to read data from a video digister in to the computer
through the port, (The printer port is in use for something else) I understand
that the port should not be loaded with any data unless the rom select line is
pulled low, The question is this,
How do I do it? My C is not very good but I can understand it, any
help would be gratefully received, example even better,

Dave Johnson.

285. 68020 "accelerators" - opinions, etc?

Newsgroup: comp.sys.atari.st.tech
Date: 1990-09-19 15:07:08 UTC
From: pms@vicorp.com
Message-ID: <1990Sep19.150708.4806@vicorp.com>
Source record: 50225

I recall reading (can't recall where) a review of three or four 68020 accelerators for the ST; the reviewer concluded that you won't really get much speed increase out of such things, with one exception: one of the accelerators included a small (32K?) cache, and this accelerator actually did provide some speed increase.
Why am I telling you this? Because I've seen no discussion of such things on the net (not that I couldn't have overlooked them :), and I'd be interested in hearing what people think about putting an '020 in an ST.
Have you any experience with any '020 accelerator for the ST? Which one(s)? Was your experience good, bad, ugly? Did you get your money's worth? I recall the prices being fairly low - ~$200-300 US.

Anyone?

-Peter

286. 68030 cache, write-allocate, and everything.

Newsgroup: comp.sys.atari.st.tech
Date: 1990-09-19 18:52:43 UTC
From: apratt@atari.UUCP
Message-ID: <2308@atari.UUCP>
Source record: 50226
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

Okay, for you chipheads out there, here's the scoop:

The 68030 design bug I mentioned is in the cache logic. I/O space must be non-cacheable, so there's an INPUT to the 68030 called "CIIN" for Cache Inhibit INput. That line is checked on all reads, but it is NOT checked on writes.

There is a bit in the cache control register called "write allocate:" when set, some writes to memory create an entry in the cache.

If you write to I/O space with the "write allocate" bit on, the write can cause a cache entry to be created, even though the memory in question is non-cacheable. A subsequent read from the same address hits the cache before the CIIN is checked, so you get stale data.

This only happens when you do a longword write at a longword boundary in I/O space, then read back any part of that longword before the cache line is re-used. You will read what you wrote, instead of reading what the device puts in its register. If it's a read/write register that the device doesn't change, you won't notice, but if it's the kind of register that means one thing when written and another when read, or if the device changes the value in the register, you will get bitten.

To fix this problem, we use the MMU to map all addresses to themselves, but we set the "cache inhibit" bits for I/O space. The MMU's "cache inhibit" bit *does* get checked on writes, not just reads. This does not affect performance (much) because the MMU has a cache of its own, to remember recently-used address translations. Almost the whole table used by TOS fits in this cache, so the MMU won't be walking through memory very much translating addresses. We've timed it, and it just doesn't hurt that much: maybe 1%.

The write-allocate bit is used by TOS so you can access the same memory in user mode or super mode and it won't confuse the cache. If you don't set the write-allocate bit, you could write something as supervisor, write it again as user, then read it as super and get the value of the first write, not the second one. This is a side-effect of the write-allocate bit, not its primary purpose.

It's hard to find, but all this stuff is in the 68030 manual: the section in Chapter 6 (the cache) called "Write Allocate" is on point, as is the whole MMU chapter. Don't get clever with the MMU, though, because we're likely to want to use it in the future.

288. AERCO board hacking

Newsgroup: comp.sys.atari.st.tech
Date: 1990-09-19 22:41:06 UTC
From: feat@max.bnl.gov
Message-ID: <2139@bnlux0.bnl.gov>
Source record: 50227

I think I've seen it asked a few times, but never seen anyone give
the details:
What has to be done to the AERCO ram board to rework the 256K bank
to use 1M parts? The sockets are the right size (yes I already have 2M worth
of chips in the other bank), but originally contained 256K parts so I believe
some trace cutting/jumpering is needed.

Also if I do get that bank active, should I worry about removing
power from the .5M bank on the (520)ST main board to alleviate the drain on
the power supply as much as possible. If so, do I have to clip the Vcc leads
of all the chips or is there a more elegant way?

Thanks.

289. Need help on floppy drive dip switches

Has anyone seen tear off menus on the Mac? They look really
neato. I'd like to implement those under GEM but I don't know how to
do it. Anyone with any ideas?

Just to be silly, I'd try to put a graphic block under the torn
menu so that when the mouse moves over the torn menu title, they see a
little clip that looks like a torn piece of paper or something. Wouldn't
that be cool? :-)

I know what you're thinking: 'Somebody has too much spare time.'
Well, it ain't me because if I did I'd be trying to figure this out myself
without asking for advice.

Thanks for any input.

John,
I haven't seen tear off menus on the Mac, but I do know of a set of software routines which enable mobile menus on the ST. It was produced within the last year or two. I found it on GEnie. I can check my disk archives to see whether I've got a copy of the archive file and then submit it to the atari.archive server.

The demo had menus which could be moved around the screen, and appeared to work quite similarly to the regular menu-bar. (It also allowed various colors in the menu...) All this is from memory, as I haven't had a chance to use the routines since I downloaded them.

>Could someone let me have further info on Quick ST and MonSTEr, ie:
>price, availablity (esp. in UK/Europe) and requirements such as TOS
>version, etc. It sounds great (you get spoiled by megapixel displays on
>workstations...)

Quick ST runs on TOS 1.0, 1.2, 1.4, 1.6, and 3.0 (TT TOS). MonSTEr requires
TOS 1.4 or higher, just like any large screen display. Both are included
on the Quick ST 2.2 package, which sells for $19.95 US. You can order it
from anywhere in the world by calling our order line and have your VISA or
MASTER CARD number ready. We can ship UPS, Express Mail, etc.

Quick ST 2.2 is not yet available in Europe, or even in many parts of the US
since it just shipped a few days ago. Your best bet is to call our number.

I recommend that if you use MonSTEr, that you have at least 1 meg of memory.
The large screen requires and extra 120K of RAM.

THe order line is 206-643-9697. It is a U.S. number.

> Could someone send me instructions on how to realign the picture on
> my sm124? It's starting to mush in towards the right. Thanks.

I recently played with the adjustments inside my SM124 and found I could do lots of things to my screen.

I now have a picture that fills almost the ENTIRE screen, although I have a teeny weeny bit of a fuzzy picture in the corners of the display.

Among the adjustments I found (Just tried them all, and most were even labeled!) were: Vert hold, move image left/right, widen/heighten adjustments...
One I am going to have to play with again is Vertical Linearity. The top row of my screen is a little taller than the bottom row of my screen.

The one adjustment I couldn't find, and wanted is the "move image up/down", cause my screen would be better if it were a "little bit" lower.

Of course I was using long plastic rods to adjust my monitor, and don't suggest to anyone that they use anything that will help them get shocked, cause everyone knows that they can hold a charge for a long time if not discharged.

In article <10562@life.ai.mit.edu> entropy@rice-chex.ai.mit.edu (enthalpy) writes:
>No! You would still have to handle the case where someone actually
>tries to _access_ data that has been paged out (you mean you have to
>be able to read it back??). This entails first of all being able to
>recognize an interrupt caused by accessing memory that was paged out

Not with the scheme I described. First, you need a table of all the
memory pages. For simplicity's sake, make it an array:

struct memptr{ word *memaddr; word statusbits; } /*sorry I don't know*/
/*how to use bitfields*/

struct memptr pagetable[4096]; /* arbitrary */

Then you need to write mallocs which don't return pointers to memory
fragments but indices into the pagetable. (actually, you need to
write something at a lower level than malloc)

int malloc(int size) { /*blah blah*/
/* figure out which block to allocate*/
/*see where in memory or disk that block really is and*/
/*set some status bits*/
return pagetableindex<<offsetbits;
}

Then you need to write a "use" function. From now on, instead of de-
referencing with the asterisk, as in *XvarPtr=1010; you use
*(deref(XvarPtr))=1010; Of course you have a macro for this kind of
call. #define use(n) *(deref(n))

void *deref(int index) {
/*look up the block by first taking the low order bits which specify*/
/*the offset into the block: offset=0x000000FF & index */
/*then you shift to find the block index index=index>>offsetbits*/
/*check the status bits to see where the block is (in memory or on disk)*/
/*if it is on disk swap something out and swap that page in*/
return actualladdress+offest;
}

Then you publish docs telling people to use the deref() func or they will
have funny things happen to their programs.

I've made this seem easier than it looks.

There are extensions you can do as well. Maybe a new func which will
set a protect bit so a page will not be swapped out, a func to unset
it, and then you can use normal dereferencing instead of handles in
```

between the set and unset of the protect bit.

This is not a nice way to have things done, but it is not uncommon.
MacOS and Windows 2 do this, as someone pointed out. Some languages
have this built in so program fragments can be swapped in and out:
instead of a pagetable there is a functiontable.

On the Epson drives, there is usually a little diagram under the jumpers showing what does what. For drive id selection there are four pins labeled 0,1,2,3 any of which can be connected to a central pin.

>
> One other thing, is there a differet switch setting if the drive
>is to be used as drive A: or drive B:?

On the ST, both drive A and B should have an id of 0 as the computer decides which one should be selected.

There's nothing special about the function "main" in C except that it is
the first function called, and it receives the command line arguments.
Variables declared in main() go on the stack just as in any other function.
Accessing local variables via embedded assembly is a bit of a pain in
general because they are referenced via offsets from the frame pointer
(in a6).

At the request of some of our users we added a feature in version 1.2 to
make this a little easier. The output of hcc now includes a comment block
at the start of each function that shows all local variables and their
offsets.

299. Data file indexing

Newsgroup: comp.sys.atari.st.tech
Date: 1990-09-21 15:29:26 UTC
From: heavy@zip.eecs.umich.edu
Message-ID: <1990Sep21.152926.28515@zip.eecs.umich.edu>
Source record: 50141

I am writing a point-of-sale system and need some advice. I have
an inventory file with appoximately 7000 records in it and I need
a way to retrieve and list records in order quickly. Right now I
have created a separate index file which basically is a binary
search tree of the key fields. Each node in the index file has
a key and a record number of the inventory record. This works
great for retrieving, I do a quick binary tree search on the index
file and get the record number, then I do a fseek in the inventory
file and read the record; it is really quick, on the average about
a second. The problem comes in when I try to list in sequence,
I have modified the index file binary search tree so that it is
linked to previous and next nodes in order, so that way I can just
skip along the index file, but it is still slow to list because
I have to fseek in the index file and in the inventory file for
each record I list. This is painfully slow on machines without
TOS 1.4. Is there a better way of doing this? I am will to scrap
my whole model if someone has a better idea that satisfies both
of my criterion...

Thanks in advance,

Richard Hall

Source record: 50236

My thanks to all who responded wrt this problem, most notably "Hardware Dave" hardware@rose.waterloo.edu, who actually had previous experience of the problem; Shoou-yu Tang (sytang@skyblue.ACNS.ColoState.Edu), who thought he did too; and also to those others who simply offered sympathy and encouragement... I'm now happily reading from my hard disk again.

The problem was indeed, as seemed likely, the old icdboot program.

For "the record", here are the specifics ---in case they are of use to someone planning an upgrade to TOS 1.4:

--> icdboot.prg version 2.1 CRASHES RELIABLY (even when it is the *only* startup) under TOS 1.4. (I went and crashed off floppy one last time to get that version number, after everything was fixed. Two bombs, if anyone counts)

--> the latest version from ICD's bulletin board (815) 968-2229, as of a few weeks ago, works fine. In particular, I am now successfully using version 4.8.4 with TOS 1.4.

--> it is NOT necessary to reinitialize the hard disk to switch.

In case it matters, the computer is a 1040 STFM with the following arcane markings on its motherboard:
C07053-001 REV. C
GX-211 V0 1986

Source record: 50144
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

I have a hard disk system that uses an ICD advantage plus host board and would like to add a tape streamer to the system. The first problem is, that I would require streamer software etc. ICD produce some software but I do not know how good this is, how I could obtain it, or how much it costs. The second problem is, what tape steamers does this or any other software recognise? (A SCSI device would be prefered.) If not a SCSI device what type of device is it (so I can arrange a suitable SCSI->XXXX board.)

I know about the existance of removerable hard disk systems but in our experiance these are not as reliable and have a much higher media cost.

Any help is welcome.

Many Thanks,

Dave Halliday

Two questions:

1. I have been trying to print out Postscript from Pagestream onto
disk, and then printing them on the NeXTs that we have here. The Problem is
that none of the text shows up in the output, only the pictures due, and also,
the postscript viewer on the NeXT show a lot of errors in the file. (I am using
just the postscript viewer, not the Encapsulated Postcript viewer)

2. Also, I am writing a DA that needs to know if there is a program
running or not. Is there an easy way to check this?

(1) Unarc micrortx.arc. Read the docs. Put the executable program in an AUTO folder.
(2) Get (or write) a multitasking shell that will work with MicroRTX.
(3) Pay your shareware fees if you like the result.

An alternative course of action, not involving MicroRTX:
(1) Get mint06b.zoo from atari.archive or comp.binaries.atari.st. Unzoo it. Read the docs. Run mint.prg (or put it in an AUTO folder).
(2) Use the provided shell and utilities. Write better ones if you want.
(3) Don't worry about shareware. It's free. (Of course, if you want to send a donation it's not going to be refused!)

>

There's always a program running (the GEM DESKTOP is just an ordinary TOS program, loaded from ROM instead of from disk). If you mean, "is the currently running program not the desktop", you might try the shel_read AES call:

```
char pgmname[128], cmdline[128];
if (shel_read(pgmname, cmdline) == 0)
printf("an error occured\n");
else
printf("the desktop thinks %s is the currently running program\n",
pgmname);
```

Note also that the desktop's idea of what the current program is may not correspond to reality, since if a program run from the desktop runs another program, there's no way for the desktop to know.

There's another problem, if I recall correctly -- shel_read() will return the name of a GEM program even after you exit, until you start another one from the desktop. I recall seeing this in a magazine article about using desktop accessories to send special messages to programs that allowed extensions that way: you can't be sure the user is actually running that program if shel_read() says it's so.

Don't know if this was fixed in TOS 1.4.

Ryan, can you tell us WHY you need to know if a program is running?

Source record: 50150

Mention was made about the shel_read() function returning a program after the program exits.

I don't know if this is true for shel_read(), but shel_find() definitely had this problem. I believe the two are related, since they both access the same portion of memory.

I believe TOS 1.4 and greater has fixed this.

I have a programming problem and I'm hoping someone here can help me.

I am attempting to play back a sample via timer A while allowing other things to go on as it plays. When the program attempts to start the actual playback it blows, sometimes displaying 4 bombs and sometimes 6. I have also tried to place the interrupt code into the main flow of the program to see what would happen. The bombs don't occur but nothing is emitted by the sound chip either. What am I doing wrong?

The code follows:

```
#include
#include

long *buff_cnt, *buff_end, *sound_chip = 0xff8800, *gi_write = 0xff8802;
char *trumpet_sound;
int snd_value,
snd_out[1025] = {
};

do_snd () {
if (buff_cnt > buff_end)
return;

snd_value = (*buff_cnt + 128) * 8;*/
*sound_chip = snd_out[snd_value];
*sound_chip = snd_out[snd_value + 4];

buff_cnt++;
}

play (addr)
char *addr;
{
buff_cnt = addr;
buff_end = addr + 58965L;
}

set_snd_chip () {
*sound_chip = 0;
*gi_write = 0;
*sound_chip = 1;
*gi_write = 0;
*sound_chip = 2;
*gi_write = 0;
*sound_chip = 3;
```

```
*gi_write = 0;
*sound_chip = 4;
*gi_write = 0;
*sound_chip = 5;
*gi_write = 0;
*sound_chip = 7;
*gi_write = 255;
*sound_chip = 8;
*gi_write = 0;
*sound_chip = 9;
*gi_write = 0;
*sound_chip = 10;
*gi_write = 0;
}

main () {
char *save_ssp;
int counter, read_handle;

if ((trumpet_sound = (char *) Malloc (58 * 1024L)) == 0) {
printf ("\n\n NOT ENOUGH MEMORY \n\n");
exit ();
}
if ((read_handle = Fopen ("trumpet.spl", 0)) < 0) {
printf ("\n Cannot find trumpet.spl \n");
exit ();
}
Fread (read_handle, 58965L, trumpet_sound);
Fclose (read_handle);

buff_cnt = 1L;
buff_end = 0L;

Supexec (&set_snd_chip);
save_ssp = Super (0L);
Xbtimer (0, 7, 0, &do_snd);

play (trumpet_sound);

counter = 0;
while (1) {
if (counter == 30000)
break;
printf ("counter = %d\n", counter++);
}

Xbtimer (0, 0, 0, &do_snd);
Super (save_ssp);
}

314. Programming problem

Newsgroup: comp.sys.atari.st.tech
Date: 1990-09-24 16:17:29 UTC
From: paulr@syma.sussex.ac.uk
Message-ID: <3505@syma.sussex.ac.uk>
Source record: 50154
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

I've been trying to get a simple program working on an Atari ST using FastBASIC. The idea is to connect a heart rate monitor to a suitable input (parallel port status line or serial port handshake input) and use a VBI interrupt routine to count heart beats. Unfortunately I get a crash as soon as I install the VBI interrupt routine, so I guess I must be doing something wrong. Since I don't normally program Atari ST's and I have no debugging tools and very little information at my disposal I was wondering if anyone could cast their eye over the following short test program and see if they can spot where I'm going wrong. The program halts with a bus error at the CALL to "init".

Thanks in advance,

//Paul

315. Re: TOS 1.4 vs old (1988) ICD HD utils [solved]

Newsgroup: comp.sys.atari.st.tech
Date: 1990-09-25 00:18:34 UTC
From: pesch@pa.reuter.COM
Message-ID: <413@saxony.pa.reuter.COM>
Source record: 50155

[I *think* this didn't make it out the first time; apologies if I'm wrong, and cluttering up the net.]

My thanks to all who responded wrt my problem (TOS 1.4/old ICD utils incompatibility), most notably "Hardware Dave" hardware@rose.waterloo.edu, who actually had previous experience of the problem; Shoou-yu Tang (sytang@skyblue.ACNS.ColoState.Edu), who thought he did too; and also to those others who simply offered sympathy and encouragement... I'm now happily reading from my hard disk again.

The problem was indeed, as seemed likely, the old icdboot program.

For "the record", here are the specifics ---in case they are of use to someone planning an upgrade to TOS 1.4:

--> icdboot.prg version 2.1 CRASHES RELIABLY (even when it is the *only* startup) under TOS 1.4. (I went and crashed off floppy one last time to get that version number, after everything was fixed. Two bombs, if anyone counts)

--> the latest version from ICD's bulletin board (815) 968-2229, as of a few weeks ago, works fine. In particular, I am now successfully using version 4.8.4 with TOS 1.4.

--> it is NOT necessary to reinitialize the hard disk to switch.

In case it matters, the computer is a 1040 STFM with the following arcane markings on its motherboard:
C07053-001 REV. C
GX-211 V0 1986

Tony! I know that about the main() function now... It is just
that I wasn't too much into C, I'd rather do stuff in assembly. Anyways,
I stumbled across the finding when I looked at dissassembled *.O file
which of course had main() and main would do a link a6,#0 (or -something
if it had any arguments). It was surprising to me, because I never
thought of main() as being just an ordinary function...

|
| buff_cnt++;
|}

[...]
|main () {
[...]
| Xbtimer (0, 7, 0, &do_snd);
[...]
|}
```

Your do_snd routine must be coded as an interrupt routine; that is, it must end in a rte instruction; not only that, it must also mark (clear?) a bit in the I/O range (sorry, have to look this up), otherwise the system will think the interrupt is still pending (actually, I think the peripheral chip is thinking this 8-). For an example, take a peek into the ROMs to see how the system timer (timer C) is coded (the I/O address I mentioned is different, but you'll get the picture).

Alternatively, you can do it the easy way, forget about programming it yourself and use the Xbios function Dosound() (but I assume there is a special reason you cannot use this?).

And if you experience spurious interrupts using Xbtimer(), I got a solution for this too (8-).

Cheers,
Leo.

P.S. The 4 bombs (illegal instruction) confirm that a wild jump was taken; this is because your code pops a return address off the stack where there is a status word and a return address.

The sequence for timer A is (I looked it up):

```
my_timint
... do your stuff here ...
bclr #5,$fffa0f
rte
```

The documentation I have says that in order to clear a bit in a MFP register, you have to write 1's into the other bits; this is in contradiction with the above (which is analogous to the ROM code). The bclr instruction to memory does both read and write a byte (correct me if I'm wrong), but this does not guarantee that 1's are written to the other bits (they must have been there already).

The explanation for this instruction was something like: the 68K notifies the MFP that interrupts may be delivered; I wonder what happens if one is being delivered before the rte (this is theoretically possible, and my spurious interrupt problem seems to indicate practically too).

Leo.

> bclr #5,$fffa0f
> rte
>

This sequence is correct - I have had no problems using it. I've never seen any documents to suggest that 1s have to be written into the other bits of the "interrupt in service" register. As I understand it, when the MFP gets an interrupt, it will not signal the 68000 unless it is of a higher priority than those already in service. Similarly, if it does signal the 68000, the 68000 will not service it unless the IPL has been moved back below 6 (?).

So, for general purpose, multi-level interrupts, the order of events should be:

```
int: move.w #$2300,sr /* Also enables VBI, #$2400, disables VBI */
.. your own thang
bclr.b #n,MFP_ISR[AB]
rte
```

On the subject of sampled sound drivers, as I understand it, to plug a value in a volume register you first do a register select and then you plug the data in. This can be done with a movep.w, right? Wanting to speed up his sample player, a friend of mine discovered that the sound chip only decoded the lowest bit of the address - so the CONTROL/DATA register pair were replicated throughout the address space of the chip. This means that rather than doing three movep.w instructions, you can get away with a movep.l and a movep.w. Of course, this can't be guaranteed to work.

Dave.

The upgrade for MINIX 1.5.10 includes the code I originally added to read the several different clocks found on HD interfaces. All are the same clock chip, just at different SCSI addresses and read funnies. Supported are/were: BMS-100; BMS-200 Supra and ICD. Unless ICD changed it it should be there. What I did was disassemble there clock read program (the one that sets the Atari clock) and then stick in a .s program that actually reads the clock into the MINIX kernel.

I think you mean DB not CSD. (At least my CSD does not do this).

MWC db plays with tos data that was 'private' in tos 1.0.
Afterward, tos 1.1 and on have a formal table of pointers to this info.

Some one at MWC got carried away and coded it roughly as:
if(tos1.0) {
there is no table , rough it;
}
else if(tos 1.1)
goto ok;
else if(tos 1.2)
goto ok;
else
goto h..l;

Use a binary editer to look for the date string of the releases and patch
the latest one to what tos1.4 uses [hint: change offset 0x1a0d from 22 to 6;
change offset 0x1a0e from 87 to 89]. Then db will work. Sort of.

It corrupts the system clock, and the console and memory are screwed
until you reboot.

Isn't nice when the OFFICIAL developer software is not compatible with 1.4,
AND MWC claims that it is.

I have been reading a disassembly of part of a program that I use frequently
and found the following XBDOS call in the code...

```
move.l a0,d1
move.w #9,d0
trap #2
```

I know trap 2 is used to call extended BDOS functions like AES and VDI,
however the books I have only list the following XBDOS function codes...

```
d0 function
-- --------
00 System Reset
73 VDI
C8 AES
```

Does anyone (maybe someone at Atari) know what the XBDOS function code 9
does? Is there a complete list of valid (Atari approved) XBDOS functions?

The cookie jar is an area of memory. Any program can insert its
cookie into the cookie jar. Then other programs can scan the cookie
jar to see if that program has been run. A program which installs
memory-resident code can use this to recognize that it has already
been installed, so it won't install itself twice. Another program
which relies on features of a specific memory resident programs (for
example, one which extends the Bios) can make sure that program has
been installed.

328. the cookie jar: a sample program

Newsgroup: comp.sys.atari.st.tech
Date: 1990-09-30 20:59:00 UTC
From: 7103_2622@uwovax.uwo.ca
Message-ID: <7204.27062454@uwovax.uwo.ca>
Source record: 50168

There have been several requests for information about the cookie jar.
Here's a sample program to print all the cookies in the system. It
illustrates how to read the cookie jar. Putting cookies in the jar is
somewhat more complicated, since under TOS 1.4 and lower you have to
install a reset vector to make sure the cookie jar pointer is cleared on
a warm boot. The MiNT source code has an example of how to do this.

If you have TOS <= 1.4, and no TSRs, there won't be any cookies. If you have
TOS 1.6 or higher, or are using MiNT, there will always be *some* cookies.

329. Upgrading Mega 2 to 4.

Newsgroup: comp.sys.atari.st.tech
Date: 1990-10-01 07:17:46 UTC
From: jackin@vehka.uta.fi
Message-ID: <1599@kielo.uta.fi>
Source record: 50169

I have a Mega ST 2 which I am planning to update to 4 MB.

I have now 16 empty sockets available, but putting 80ns
chips didn't work. It was quite expectable original chips
being 150ns.

Do 120ns chips work or do I need 150ns (rare in 1MB chips) ?
Is there anything else to do apart putting chips in and
soldering capasitators (as is done in original 2 MB) ?

I wanna see my Spectre work with 4MB !!!!

Thanks,
Markku

First of all, I dont't see any reason why 80ns chips shouldn't work. However,
you might have a few resistors missing for the second DRAM bank. These resistors
are put in series with CAS and RAS lines (and R/W ??) connected to the MMU chip.
Some motherboards have them installed, even on Mega 2 boards, but some don't.
See if you can find them..

If you want to know what speed your old chips are, please mail me the type#
I'll see if I can find them in the databooks.

Good luck,

entropy@mole.ai.mit.edu (Nick Castellano) writes:

>Dunno, I've never had to use it. Anyone else? The question is:
>Where is the cookie jar, or how does one find out where it is?

Look at the contents of $5A0.L to find out the start address of the
current cookie jar. If it's zero, noone has installed it yet, and you
will have to do that yourself. The cookie jar is always terminated
by a special cookie. Like all the other cookies, its length is
8 bytes (4 bytes for identification of your program - much like
XBRA IDs; IDs starting with an underscore are reserved for ATARI;
some program-specific info follows the ID). The ID part of the
last cookie is always a zero longword, and its data part gives
you the size of the current cookie jar in units of cookies (8 bytes).
If you find out that inserting your own cookie would result in

memory overflow you must allocate a cookie jar of your own and
keep it resident.

> Do 120ns chips work or do I need 150ns (rare in 1MB chips) ?

Yes, they should work, I have 100ns chips in my expanded 520.
80ns may be pushing the refresh rate, but I haven't looked into it.
I believe there was a note about it on c.s.a.st last year.

> Is there anything else to do apart putting chips in and
> soldering capasitators (as is done in original 2 MB) ?

I hope someone else expands on this as I can only suggest things from possibly faulty memories (my own, not the ST's 8-). 1) You need to have all the correct resistors in place for things to work. 2) I seem to recall that Atari sent out some Mega 2s that have faulty MMUs, i.e. they can only handle 1 bank instead of the regular 2. The numbers of these chips are known, and I might be able to dig the article up (US ST World I believe) if no one else can elaborate on this. If you want to do something about this *now*, and have access to a working Mega 4 or upgraded Mega 2, open it up and note the MMU numbers and look for resistors (RAS, CAS, etc. for bank 2, there are plenty of them I believe) that are not in your Mega. Add any missing resistors (correct values and tolerances please, just match the color codes or markings) and if it still doesn't work, swap MMUs. BTW, does it still work properly with 2Meg? In any case, please check your soldering again for bad (cold) solder joints and for "bridged" traces.

> I wanna see my Spectre work with 4MB !!!!

Me too, but I need a Spectre 1st, then the new memory board and xtra 2 Meg 8-).

A while ago, someone posted a short Turbo C program to this group on "how to use GDOS fonts without having GDOS loaded". Well, I can't get that program to work under Laser C; I suspect Turbo is using some font definition structure I don't know about.

Has anyone managed to get this program to work under Laser C? Or some other ST C platform that uses more conventional structures? Any information (or actual source code B-) would be appreciated.

YES!! You need to add 3 resistors (33 ohm) in the area surrounded by the
existing RAMs, ROMs and the boards edge; somewhere around R61 if I remember
correctly. There are at least 3 missing resistors there...

In the documentation that came with my 1040STFM, theres a pinout
on the monitor port labelled as 'audio in'. I havent heard of anything,
software or hardware that uses this, and I dont even know what it does,
if anything. Does anyone know what it can be used for, and if so how
can I go about it ?

I was hoping thered be someway to digitise with it, with the addition
of little or no hardware support.

Mithrandir.

There are no unallocated slots in a cookie jar. If you want to delete
a cookie once installed you must compact the cookie jar.

>> TOS 1.4. He recommended against trying, for example using the binary patches

Ok, here's what changed. Mark Williams Company has a MAJOR hit in their COHERENT operating system for PC compatibles. It gives people a chance to try something VERY UNIX-like for a reasonable price. As a result, the resources they were going to devote to fixing db properly will not be available (that means that the guy who would have had to do the work has been drafted for an upgrade to COHERENT). 3WThey also inform me that Atari has been less than cooperative about helping them with the fix for new TOS versions. A debugger really DOES have to do things that most developers are better off not even suspecting are possible. When the wait was maybe a few months for a proper fix, that was tolerable (to me; maybe not to you). Now the word is probably never.

I'm trying to be happy for a group who put out a product I like very much, and who still are happy to go out of their way to help when I have problems with it (as long as I telephone for help rather than writing).
Steve J.

Hi,
I have a 1MB Atari ST which I use at home. At work I read the SUN group mail/news and there it seems folk are upgrading various Sun machines cheaply and quickly to have 4x the memory, often 8MB to 32MB, by plugging in 4MB SIMMS.

I wondered if it is possible to do this on an Atari ST - just remove all the chips and replace them with 4MB ones. Please email me directly as I don't read these groups.

many thanks

342. Re: Does TOS convert CR to CR/LF on printing?

Newsgroup: comp.sys.atari.st.tech
Date: 1990-10-03 17:28:58 UTC
From: jimh@ultra.com
Message-ID: <1990Oct3.172858.287@ultra.com>
Source record: 50179

Well, I got considerable mail from this, and I guess I didn't
word my original problem very carefully.

Anyway, I have the solution and I'll explain things in a little
more detail now that I have the complete picture (or at least
a sharper image).

Problem #1: I had patched my Desktop.Inf file so that all
double clicks on non-programs would call the 'more.ttp' program
from Moshe Braner. I had done this for so long now that I
forgot about the Desktop Print capability.
Solution #1: The Desktop Print command does indeed print in binary
form and does no conversion on the input files.

Problem #2: I didn't realize that TOS Shells had access to a device
driver called PRN: like IBM DOS. Maybe it's just me, but I don't recall ever
reading about this. Therefore, I was using shell commands like 'lpr'
to do my printing. These drivers were assuming that the files ending
in a single CR were UNIX-like text files and converted them for me
to CR/LF.
Solution #2: Use the equivalent of 'cat file > prn:' in the shell.
This works fine in both gulam and MT C-Shell.

This seems to be a regular question so I'm posting this list.

Bombs Meaning Possible cause
2 Bus error Access non-existent memory
3 Address error Word/Long access to an odd address
4 Illegal Instruction Bad opcodes (JMPing into data!)
5 Divide by zero Left as an exercise for the reader :-)
6 CHK Instruction Ditto
7 TRAPV Instruction Ditto
8 Priviledge violation Priviledge instructions in user mode
9 Trace Trace!
10 Line A Trap $Axxx opcode - used be system
11 Line F Trap $Fxxx opcode - used by system
>11 Unassigned/Interrupt/Trap Bad interrupt/trap

On my old ST (1986), addresses up to $3fffff (4Mb) are accepted even if
the memory doesn't actually exist - so you may not get a bus error
even if you're expecting one.

Hope this helps alot of people.

Dave.

Message-ID: <1990Oct4.134038.23351@dgbt.doc.ca>
Source record: 50187

I am writing my own shell program in Sozobon C. (I want it
to be less than 20 K on my 1040Ste Ram Disk and have the features
I want.)

I can execute another ttp or tos file from this shell
using the Pexec command; however if that ttp program crashes it
also crashes my shell program returning the system back to GEM.
If I run the same ttp program program on another shell (eg Gulam)
it still crashes but it returns back to Gulam so I can see
any of my printouts.

Can anybody tell me what other setup I must do so that I still
return to my shell program in event of a fundamental error in
my new program. Sample C code or the source code of a public domain
shell program would be helpful.

In article <`$R%X?_@rpi.edu> onders@degas.ipl.rpi.edu (Timothy E. Onders) writes:
>In particular, what do 3 bombs mean? Does anyone have a list of the
>different bombs?

Bombs occur when the 68000 takes an unexpected exception trap. The
number of bombs is equal to the exception number. The more common
ones:
- 2 bombs is a bus error, usually occurring because you accessed
non-existent memory, often because of using something as a pointer
that wasn't a pointer, or wasn't initialized.
- 3 bombs is an address error, meaning that you accessed a word
or long word operand at an odd address. May have similar causes
to a bus error.
- 4 bombs are an illegal instruction, which probably means your
program took a wild jump an started executing data.
- 11 bombs is an F-line emulator, meaning that your program tried
to execute an instruction starting with the bits "1111...'.
These instructions are reserved for the co-processor (which
doesn't exist in ST's. It probably means your program took
a wild jump into an area of memory that was filled with all
FF's

If you see a large number of bombs, it may indicate that more than
one exception happened.

>In particular, what do 3 bombs mean? Does anyone have a list of the
>different bombs? I used to have one but I can not find it now.

The number of bombs is equivalent to the number of the 68000 exception which occured.

Note that if the ST gets an error while (or just after) it is drawing bombs, it will sometimes draw bombs for the 2nd error as well (on the same "line"). For example if you see 11 bombs it is most likely that two errors occured, for example; 5 bombs followed by 6 bombs.

-< Description of BOMBS >-

This description of ST bombs was originaly posted to the Usenet by Andie Ness. I've added a comment on large numbers of bombs.

Here's a list of what the various numbers of bombs mean...

1 - Impossible. If you get 1 bomb, take your ST to a repair shop.
2 - Bus error. This means you have tried to access memory outside the computer's valid address space (or tried to access a protected area in user mode).
3 - Address error. This usually results from doing a word or long operation on an odd byte boundary.
4 - Illegal instruction. You figure it out.
5 - Divide by 0. Usually generated by the divs and divu instructions, though if I recall correctly some others can cause it as well.
6 - CHK instruction trap. If a chk instruction returns an illegal value, this trap is executed. Chk is actually pretty dumb, in my opinion, unless you're using Pascal.
7 - TRAPV instruction. You get this by executing a trapv instruction when the overflow bit is set. Most programs don't use trapv, so this one shouldn't pop up much.
8 - Privilege violation. This one appears when a supervisor-only instruction is encountered in user mode.
9 - Trace. If you've got the trace bit set, this trap will occur after each instruction. Great for debuggers.
10 - Line-A. You shouldn't get this, as it's the interface Atari uses to get to graphics routines.
11 - Line-F. This is supposed to be a hook for math coprocessors, but Atari (DRI?) used it for GEM instead. I would have preferred a coprocessor.

The others are pretty much undefined; if you get one, something weird is going on. From 32 to 47 bombs mean that you made a trap call whose vector

wasn't set.

From: jackin@vehka.uta.fi
Message-ID: <1624@kielo.uta.fi>
Source record: 50094

Thanks to all who responded my question about Mega 2 --> 4.
I will try it again maybe this weekend.

Now for a weird problem: My diskdrive seems to have some trouble
writing at 8 sectors/track with GCR. It may do so for a long time
and then stop doing it. So far I have fixed it with a blow of my
fist (a few G's a day keeps the errors away :-). Errors are allways
on the first side. To me it looks like a mechanical problem, true ?

I am not sure what type of drive I have. I did try to check it out,
but couldn't find a name on it. (yes, I did open the case)

Has anybody had similar problems ? Do I need to change my DD :-(

Thanks,
Markku

> makers or Spectre.
> Email is never replied upon, an airmail letter apparantly faced the same destiny
>
> As a last resort, I tried sending a fax. And this didn't work either.

There are several things that have could be causing your problems.
First the system that gadgets is fed from isn't the most reliable in the
world (it's a dying 7300). There have been lots of problems with email
and netnews for the last few months. Gadgets is looking at getting
another feed (probably uunet), but it will be awhile before that happens.

As to the letter and the fax you may have just picked a bad time,
Dave and Sandy were gone for over a week last month (computer show and
a short vacation with the kids). They are back now but are busy getting
ready for the next release (version 3.0) so they may not have answered all
their waiting mail and fax messages yet.

The most reliable way to contact Gadgets is phone (voice or
fax), unfortunately that isn't a cheap option. Next best is GEnie,
in the Gadgets roundtable. Usually you will get a response the same day,
occasionally it may take two or three. Next best is either email to
the well (...!hplabs!well!dsmall or dsmall@well.uucp) or to gadgets
(...!boulder.Colorado.EDU!tcr!gadgets!dsmall). Neither of those is
very reliable, one has machine problems and they both have problems with
replies (I can't always send mail from tcr or gadgets to my work machine,
and I'm SUPPOSED to know what I'm doing ;-).

I remember a while back there was a thread about things to be aware of when writing Desk Accessories. Stuff about mallocing, file pointers, what happens to the DA when a program terminates etc. Of course, I wasn't paying too much attention to it at the time and now I need the information.

So, can someone out there please email me that material and any other "do's and don'ts" of Desk Accessory writing?

Thanks.

I think the easiest summary is "don't keep any operating system
resources tied up when you call evnt_multi". That means no mallocing
and no open files.

Then the only exception is that you can malloc memory right when you
start up, before you call evnt_multi for the first time. [In that case
the memory becomes owned by the desktop, which never exits, so the
memory never gets deallocated.]

Of course, if you're running RTX or Mint, you can do more. Then you
can arrange for another process to allocate memory or leave files
open.

[stuff]
> Has anybody had similar problems ? Do I need to change my DD :-(

Yup, me too. Supposedly, this is not that an uncommon problem for
some Mega2s. Their internal drives just don't seem to work. This problem
is that there is too much electical noise inside the computer that it
is drowning out the GCR info. Dave's solution is to wrap the cables and
the drive in some sort of shielding material and ground it. This doesn't
work for me :-(But I do have an external that, although it is really
loud, works like a charm :-)

I'm the one who raised this question a couple of months ago.

I've mailed off to comp.binaries.atari.st a completed desk accessory
for filtering MicroEMACS files into a format suitable for PageStream.
It should show up on the net Real Soon Now.

Because of the limitations on calling Malloc(), I wound up simply
tossing out the idea of vacuuming a whole file into memory before
massaging the data.

I thought I'd just use fgets() and fputs() ... but you can't do that,
either, at least not with Sozobon C, because dLibs has dynamic memory
allocation buried deep in the buffered i/o routines.

I didn't feel up to rewriting the whole buffered i/o library, so I made
do with two routines (see below) that make direct GEMdos calls. The
reading routine is horribly slow, but that doesn't seem to be a practical
problem in the DA I wrote.

The functions follow. PPerhaps someone else will find them useful.

#include <osbind.h>

/*
* Function: fhgets
* Input: Pointer to data buffer, limit on the length of the buffer,
* and a vald open GEMDOS file handle.
* Output: Fills in the data buffer if possible. Returns a pointer to
* the buffer, or NULL if end of file has been reached.
* Description: fhgets is like fgets, but it works (s-l-o-w-l-y!) from
* GEMDOS file handles. We have to write this because dLibs has
* memory allocation deeply rooted in the stdio package, and
* we want this program to run as a DA, which must not
```

```
* hold mallocked memory.
*/
char *fhgets(data,limit,fd)
char *data;
register int limit;
int fd;
{
register char *p = data;
char c[1];
register int bytes_read;

while(--limit > 0)
{
if ((bytes_read = Fread(fd,1L,c)) < 1)
break;
if ((*p++ = c[0]) == '\n')
break;
}
*p = '\0';
return((bytes_read <= 0 && p == data) ? NULL : data); /* NULL == EOF */
}

/*
* Function: fdputs.
* Input: pointer to a null-terminated array of char, and a valid open GEMDOS
* file handle.
* Output: Sends the string to the file and returns the number of bytes written.
* Description: Works like fputs. A newline is not appended.
*
*/
int
fhputs(s, fh)
char *s; int fh;
{
return (Fwrite(fh,(long)strlen(s),s));
}

Hello.

Can anyone explain me why more bombs should indicate several traps
in a row? As far as I understand the drawing-routine, it always
starts from the left, thus painting the bombs one over another.

One thing I know for sure is, that running RTX-programs w/o having
the RTX-Kernel installed yield a row-full of bombs (40). I think
Signum! uses the same vektor.

363. The program's name and path - how can I get them?

Newsgroup: comp.sys.atari.st.tech
Date: 1990-10-08 10:03:46 UTC
From: klute@heike.informatik.uni-dortmund.de
Message-ID: <1990Oct8.110346@heike.informatik.uni-dortmund.de>
Source record: 50103

Due to public demand I would like to integrate a functionality into Arcgsh (you know - the GEM shell for Arc, Zoo, LHarc etc.) that allows you to doubleclick on e. g. FOO.ZOO which causes Arcgsh to be executed and immediately showing the Zoo parameter dialog box with FOO.ZOO already filled in as the archive name.

However, what I need to know is the complete path of the executing program. This is neccessary to read (resp. write) the configuration file which is in the same directory as the program itself. I played around a bit (using TOS 1.4) with shel_read() and shel_find(), but I am not satisfied with the results:

- Shel_read() works reliably only when the program is called from the desktop. When it is called from a shell it may return the name of that shell.

- Shel_find() needs to know the program's name in order to find out its path. It works alright if I hardcode the program's name, like
strcpy (buffer, "ARCGSH.PRG");
shel_find (buffer);
but will fail if the program is renamed.

Another observation is that loading the resource file always worked with rsrc_load ("ARCGSH.RSC").

Does someone have a general solution? It would be sufficient to get only the directory where the program is located - without knowing the program's name. Even better would be a possibility to retrieve the program's name also, and the best would be if this could be done without GEM functions. And yes, of course only legal solutions are useful.

>

I don't think there is a legal solution that always works (and the illegal ones involving looking for variables in the parent's basepage certainly break under multitasking systems, and probably on the TT as well). However, a combination of legal solutions may work most of the time:

What I usually do is look at argv[0] in main(); gcc, MWC, and many other compilers will fill this in with the program name if run from a shell that supports the Atari ARGV= extended argument passing scheme. Note: some shells will put only the program name (e.g. "arcgsh") in argv[0]; if so, then you'll have to search the directories given in the PATH variable to find the complete program.

If argv[0] is invalid (see below), then the best bet may be to look for a PATH environment variable and search along it for your configuration file, and/or use shel_find or shel_read. Almost all shells will set PATH, so if no PATH is found and an invalid argv[0] is present then the program was probably run from the desktop, and so the shel_* functions ought to work.

The ANSI standard says that argv[0] should be an empty string if the program name is not available; the new gcc library does this. The old (1.27) gcc library used to put "a.prg" in argv[0] by default, and some compilers may put "a.out" there.

>name. Even better would be a possibility to retrieve the program's name
>also, and the best would be if this could be done without GEM functions.
>And yes, of course only legal solutions are useful.

DO NOT (repeat) DO NOT use the horrible hack introduced in the dlibs
startup code. It dies completely under RTX, and MiNT takes precautions
to make sure that it does not work. There is _no_ legal way that I know
of that you will always be able to do this. You can check to see if
the program was started from a shell which supports the ARGV= protocol,
but that's about it.

367. ZOO.ARC - Help

Newsgroup: comp.sys.atari.st.tech
Date: 1990-10-08 15:30:01 UTC
From: jharres@sleepy.bmd.trw.com
Message-ID: <805.27103909@sleepy.bmd.trw.com>
Source record: 50108

HELP! I got zoo.ttp from the umich archive (thanks) but have been unable to get it to unarc a program. I used binary mode to ftp it without any problem. I then unarc'd it (with arc.ttp that i ftp'd during the same session) and got the six or so files. The command I input was "zoo x passm.z". Zoo's response was a couple lines showing the correct commands. I couldn't get "zoo h" to show me anything different. With it showing me potential command inputs I assume the program is capable of running, but isn't getting the right input from me. The instructions (yes I read them :^)) didn't give me a clue as to what is wrong.
thanks in advance

Jim Harres jharres@doc.bmd.trw.com

368. More on DA's

Newsgroup: comp.sys.atari.st.tech
Date: 1990-10-08 17:08:49 UTC
From: heavy@zip.eecs.umich.edu
Message-ID: <1990Oct8.170849.14843@zip.eecs.umich.edu>
Source record: 50109

With the recent discussion about DA's not being able to use system resources before going back into an event_multi, I thought I had my problems beat. I was opening files and then calling event_multi in my DA and the system was locking up. So I decided to change the way I do this and close the files before I went back to the event_multi, well, this still locked up the system.

Basically all I am doing is trying to open a dialog, get interaction, and then do something in a file, close the file, close the dialog box, then exit the DA and wait for another AC_OPEN.

Should this work?

369. STe DMA sound playing

Newsgroup: comp.sys.atari.st.tech
Date: 1990-10-08 18:26:54 UTC
From: dmb@wam.umd.edu
Message-ID: <1990Oct8.182654.25278@wam.umd.edu>
Source record: 50110

Could the individual(s) who collected documentation on STe DMA sound playing please send it to me (or point me to it)? I'd like to get my sample playing utilities (beep, click, play, etc.) working with STe DMA sound.

Also, I'll need beta-testers since I don't have an STe (!). Any volunteers? (C'mon, you KNOW you want to be the first on the block to have a real live 8-bit digital keyclick!)

Thanks!

You have a BMS-100 controller. its Great, but not perfect.
Likely you will need the BMS-200 (a $75 upgrade). Give them a call;
they are very knowlegable, and probably know just what is happening
with your Conner drive.

Which command-line interpreter are you using? Some of them, such as PCOMMAND,
convert all text into uppercase. Zoo expects many of its options in lowercase.

You can use the basic functions of Zoo with CLI's such as PCOMMAND thusly:

Zoo -list <zoofile>
zoo -extract <zoofile>
zoo -print <zoofile> file-to-read

If you are using Gulam, you shouldn't have the above problem.

|but that's about it.

Well, there _is_ a legal way that I know of, but you may not like the implications. Just write a TSR that traps Pexec calls and saves the filename in a private buffer before letting GEMDOS take over. By some communication with the TSR (various ways to do this) the newly started program can find out its real name.

Some potential problems (and solutions) with this scheme:
a) In case of a relative pathname the TSR must prepend the current directory in the private buffer. Piece of cake.
b) the application must check for the TSR to be present, and if it is not, (perhaps install it and) exit with an error message to do a retry. Not so big a problem, since the user will probably put the TSR in his AUTO folder if he needs it frequently.
c) In case of a multiTOSking environment, there is a potential race condition between the new program getting its full path and another program being Pexec'ed at the same time (overwriting the static buffer). If you want to solve this, you'll probably need multiple name slots.
d) With Pexec(4,...) (go) you don't supply a name, so you can either take the easy way out by aborting the program, saying you don't support preloading, or keep the name supplied by Pexec(3,...) (load) together with the basepage address - this might imply maintaining a list.
e) If the executing program is not a disk file, it will not even have a complete path (take the Desktop for example). This is really not a problem for most application programs.

Leo.

Hello!

I was wondering if anyone would care to comment on the Zubair Z-RAM memory upgrades for the ST. In particular, I have a 520STFM and would like to upgrade to at least 1 meg, but having 2.5M for under $300 is tempting. Also, it appears from the ads that it is a "solderless" instal, is there any difficulty in replacing the clips with hard solder connections?

Looks like you're trying to use zoo on a Unix 'compress' file - zoo files
will end in .zoo, compressed files in .Z. You should either uncompress it
on your Unix system or get the compress utility from atari.archive/panarthea
and do it on your ST.

Zoo is case-sensitive. Because the desktop puts everything into uppercase
before passing it on, zoo is barfing on what it considers bad input. The
temporary workaround is to use the "novice" commands, which can be accessed
by using a minus sign before the command, e.g.

-list whatsit.zoo

will list all the files included in whatsit.zoo. Extractions can be done
with the -extract command.

The better approach is to get hold of a shell (like gulam) which doesn't
mangle the case of the arguments it passes. If it can do wild card
expansion, so much the better.

Now for a question of my own: Is there a command to zoo that will cause
it to archive the contents of a subdirectory, including any subdirectories
of that subdirectory, and their contents, in a recursive fashion? I've
already RTFM, but either I was extremely dense that day or it's not there.

378. Using 5 1/4" Disk Drives (Summary)

Newsgroup: comp.sys.atari.st.tech
Date: 1990-10-09 23:29:49 UTC
From: crichmon@digi.lonestar.org
Message-ID: <1094@digi.lonestar.org>
Source record: 50115

I got the following responses concerning where to get a
5 1/4" disk drive to use with an Atari ST and read the IBM
360 k format disks:

- -

I was told that not all 5 1/4" drives will work. (No mention
of why or what type of drives will not work.)

- -

Regardless of which 5 1/4" drive you use, the track to track
stepper rate must be reduced to 6 milliseconds. There is a PD
program to do this; also, most 5 1/4" drives designed for the
Atari ST come with this type of program. It works by poking
the stepper rate into memory. On TOS 1.4, there is an xbios
call that does this instead. (This is a more stable solution
and less likely to change in the future TOS releases.)

- -

E. Arthur Brown [at (612) 762-8847] sells a special cable
and software to lower the steppper rate to 6 milliseconds.
The cost is $39.95, and presumably it can be used with an
external drive designed for use with an IBM PC.

- -

One person told me that Indus made a GT-1000 model 5 1/4" drive.
It has a track indicator and a write protect button. He said
it worked great with his ST, but it would have trouble working
with an STE. A local dealership told me that Indus was out of
business.

- -

Another person suggested that I take an IBM 5 1/4" drive and
swap the circuit cards with an Atari ST 3 1/2" external drive.
He claimed that would require unhooking and reconnecting a
ribbon cable only. Of course, the stepper rate must again be
set to 6 milliseconds.

- -

A local dealer sells a drive made by a company called IB.
It is the model 909 and retails for $225 with power supply.
Another local dealer said that he built up his own 5 1/4"
drives for the Atari ST with power supply for about $200.

Check your local dealer; your mileage will vary.

- -

Someone from Atari in California suggested that I look for a drive made by Atari called the model PCF-554. Another local dealer told me that these were made for Federated to sell with the Atari ST's and PC's. If you can find one, it should work okay with the 6 millisecond track to track setting. Since Federated is defunked, probably you won't find one.

379. Hard Disk Formatting Software and Info

Newsgroup: comp.sys.atari.st.tech
Date: 1990-10-09 23:36:22 UTC
From: crichmon@digi.lonestar.org
Message-ID: <1095@digi.lonestar.org>
Source record: 50116

Can anyone tell me where I can get some hard disk formatting utilities? (I have no anonymous FTP access to the NET.)

I plan to replace the 20 meg drive in my Atari hard disk with an 80 meg drive. I will need different formatting software to format and segment it properly.

Can anyone give me some references to books or magazines that describe how the hard disk is formatted and segmented for the Atari ST? It would be even better if you could send me some of this information directly. (I seem to vaguely recall that David Small had an article on the way the ST formats hard disks in one of the ST magazines--can you tell me which it is?)

Thanks in advance for all your kind help.

Charles Richmond crichmon@digi.lonestar.org

380. A Mac Emulation question....

Newsgroup: comp.sys.atari.st.tech
Date: 1990-10-10 00:36:02 UTC

382. Using ZOO to backup and restore/create relative subdirectories

Newsgroup: comp.sys.atari.st.tech
Date: 1990-10-10 14:36:38 UTC
From: steve@thelake.mn.org
Message-ID: <A1284707658@thelake.mn.org>
Source record: 50125
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

There have been a couple of (unanswered, I think) questions lately about how to use zoo.ttp to automatically archive subdirectories and to automatically create subdirectories relative to the current directory when unpacking files.

There are two so-called "novice" commands to do this. They are not explained in the helpscreen that appears when you run "zoo h".

The commands are:

zoo -backup file.zoo *.*
This packs everything in the current directory and all relative subdirectories, preserving the (relative) path information.
^^^

Welcome back!

> First: What products are currently available and where can one get
> information on them?

The best and only is Spectre GCR from Gadgets By Small. It uses 128K Mac roms to emulate a Plus and is able to read normall 400k/800k Mac disks right in your normal Atari drives, no modifications!

> Secondly: What kinds of ST system setup are we talking about to inable
> one to use these things?

Minimum of a 1 meg system (ie. 1040STe). But for serious work with Adobe Type Manager and other things you'll want 2.5 - 4 megs.

> Finally: (and most importantly for the applications I am looking for) Do
> any of these emulations include support for the AppleTalk system
> (Broadcasts, etc.)?

Yes, David Small is finishing the work on a AppleTalk board for the MegaSTs. This will allow you to use AppleTalk from within Spectre. The board will also include the right hardware to allow the use of Mac midi programs. Finally, the board will have a SCSI port to allow you to hook up Mac SCSI devices such as scanners, cd-roms, and hard disks.

(Which brings me to a side thought. Would this mean that with the right software on the ST side, we could hook up those nice scanners and other goodies and now have lots of peripherals for the ST??)

> Thanks in advance,
>
> Mark Hamill
> mh4x@andrew.cmu.edu

No problem. If you have any more questions just reply or e-mail!

Take care,
Marshall

> appears from the ads that it is a "solderless" instal, is there any difficulty
> in replacing the clips with hard solder connections?

I just installed a Z-RAM upgrade in my 1040ST. Installation was extremely easy - pull the video shifter chip, plug in the ZRAM board, plug the chip into the ZRAM, and plug the connector at the end of the ribbon cable into the Atari MMU. I bought the unpopulated board from E. Arthur Brown for $115, and the chips from Microprocessors Unlimited for $208 (32 of them).

One of the nice things about the ZRAM upgrade is that the same board will work with any ST, as the MMU connection is on a cable. The Tech Specialists upgrade (one of which I have installed in a 520ST) has the MMU connector on the main board, and the shifter connection on a cable, so it is highly dependent on motherboard layout.

Downside: the RF shield (that big piece of sheet metal) will not fit over the ZRAM board, so you either have to do without or cut out a piece with tinsnips. No big deal, but you are no longer class B, and you can't run the ST at home legally (FCC class B deals with residential environments).

Overall, I *love* it.

BTW, the design does *not* lend itself to soldering - this is pretty much true of anything connecting to the MMU, I think.

Hope this helps!

Max J.

385. ftpeeing

Newsgroup: comp.sys.atari.st.tech
Date: 1990-10-11 01:01:23 UTC
From: bbs@bluemoon.UUCP
Message-ID: <1cRuq1w163w@bluemoon.UUCP>
Source record: 50129

Hi all!

I just recently got an account on a VAX at Ohio State and there I got a taste of FTP. The idea is really cool <and fast!>, but I got problems anyhow. The basic problem is with getting the files ftpeed to my VAX account to my ST.

Here's why: My account doesn't have the 'privilege' of calling in to the vax from my house and the VAXstation doesn't support the ms-dos (ST compatible) format.

Here are a few solutions I tried:

--> There's a utility called pcdisk available from DCL Command which writes in messy-dos format, but High Density only (unreadable by ST--I tried it).

-->> There's a facility somewhere at Ohio State which does the transfer onto a floppy from one's account in messy dos format, but they probably got 1.2 or 1.44 meg drives too.

-->>> Sysop of Bluemoon.uucp offered to help (greatly appreciated effort), by rendering his 1.2 or 1.44 meg drive so that I could transfer files written in hd format to my ST over the modem.

The last two solutions are OK, except that I don't wanna be running around with disks like a crazy hacker all the time.

Has anybody got any other suggestions? How do you take care of your FTP?

Archbold

>got 1.2 or 1.44 meg drives too.
>
You should have no trouble reading/writing/formatting 720 K diskettes on
a 1.44 MB drive. The same is not true of 360 K diskettes and 1.2 MB drives.
The difference between a 720 K diskette and a 1.44 MB diskette is only
the sectors per track. The differences between a 360 K disk and a 1.2 MB disk
are a bit more drastic. The most important one is that the tracks on a 1.2 MB
disk are only half the width of those on the 360 K disk. You can usually
get interchangeability between 360 K drives and 1.2 MB drives, but you can't
depend on it.

388. Fixes to Sozobon JAS (btst instruction).

Newsgroup: comp.sys.atari.st.tech
Date: 1990-10-11 14:26:57 UTC
From: rfpfeile@watcgl.waterloo.edu
Message-ID: <1990Oct11.142657.26505@watcgl.waterloo.edu>
Source record: 50126

Sorry, but I seem to have misplaced the list of fixes to the jas assembler for Sozobon C that correct a problem with the btst (??) instruction translation..

It was only five lines or something, but I can't find it.

Anyone there give me a hand?

Ron

389. More on STe DMA sound (A question for folks at Atari)

Newsgroup: comp.sys.atari.st.tech
Date: 1990-10-11 16:31:25 UTC
From: dmb@wam.umd.edu
Message-ID: <1990Oct11.163125.9299@wam.umd.edu>
Source record: 50127

Many people have sent hints on playing sound through the STe's DMA sound mechanism. (Thanks everyone!)

One problem that has been pointed out to me is that only four playback rates are available: 50kHz, 25kHz, 12.5kHz, and 6.25kHz. Since these are nonstandard rates (with respect to CD's and DAT's at least), the DMA sound mechanism alone seems severely handicapped.

I have never found any samples that were recorded at these rates, and although it would be straightforward (but nontrivial) to convert exisiting samples to these rates, this sure seems like a lot of trouble to go to when we've already got 100's of megs of 11kHz and 8kHz samples floating around.

Question: Does anyone know if it's possible to use the STe DAC chip directly? In other words, is there a way I can just bypass the DMA stuff and use MFP Timer A to control sample playing (as with normal ST's)? It would be nice to have 8 bits of resolution instead of 5; the sound quality should be superior using the STe DAC than using the cheezy sound chip in standard ST's. (The Hippo digitizer is one I already support, and it sounds quite a bit better than the ST's PSG chip.) I relize that using Timer A will eat up the CPU, but I see no way around it.

Could someone at Atari please comment on this? The documentation I have on the STe's sound is vauge when it comes to poking the DAC directly. Is there a register I can just stuff samples into? (I.e., Can I just update the volume register(s) directly without turning on the DMA?)

Thanks in advance.

Dave Baggett

391. More on Laser 2.1 vs MiNT

Newsgroup: comp.sys.atari.st.tech
Date: 1990-10-12 09:18:25 UTC
From: kentd@FtCollins.NCR.com
Message-ID: <KENTD.90Oct12101825@zappa.FtCollins.NCR.com>
Source record: 50131

I've moved discussion of this topic to ...st.tech since it's getting more technical than general interest.

The following is a reply to my query about Laser C's incompatibility with MiNT. Sam Streeper writes:

From: Sam_Streeper@NeXT.COM
To: Kent.Dalton@FtCollins.NCR.com
Subject: Re: Laser C V2.1 vs MiNT??
Newsgroups: comp.sys.atari.st
In-Reply-To: <KENTD.90Oct9111745@zappa.FtCollins.NCR.com>
References: <KENTD.90Oct7182718@zappa.FtCollins.NCR.com>
<1990Oct8.144159.12610@doe.utoronto.ca>
Organization: NeXT, Inc.

>When in debug mode, MiNT shows Laser Programs malloc'ing 8K (presumably
>stack), it then tries to grab some more mem and gets a message to the
>effect of: get_region, no region is big enough or some such.

From this description, I know exactly what the problem is. The laser init code can start both programs and desk accessories. It tests something undocumented to determine which it is starting. If it is starting a program, it gives back all the memory except what it needs for a stack (using Mfree()). If it is starting a desk accessory, it mallocs a stack, but has no need to free any memory, since accessories are already "shrunk to fit" The init thinks the program is an accessory, so it is a big memory pig and all subsequent mallocs will fail.

I don't consider this a Laser bug, because all versions of TOS set this up correctly, and lots of people use this trick to get their gem applications to work as both programs and DA's. With this being the case, MiNT should really start apps with the same setup as TOS. I had to patch the original MichTron juggler to get it to correctly start Laser (and other dual purpose) programs.

If you write back, I'll check what it is that Laser init checks when I get home. Feel free to post this information; I don't really know how to do News posting...

392. Uniterm V2.0e bug when printing ???

Newsgroup: comp.sys.atari.st.tech
Date: 1990-10-12 13:51:41 UTC
From: mreiss@ncrcam.Cambridge.NCR.COM
Message-ID: <2080@ncrcam.Cambridge.NCR.COM>
Source record: 50132

I think I have found a bug in Uniterm (not real sure). I have my atari connected through an async network to several computers. Most of them run Unix.

The printer port on my atari is connected to an HP LaserJet through several layers of Centronics switches.

On the Unix computers I have a shell program that allows me to print files to the HP printer. This involves making use of the "send to printer" VT100 function (Thanks Simon). The shell program sends "ESC [5i\c" to the atari. This gets interpreted as "send what follows to the printer port, but first send a newline". It then sends the file followed by "ESC [4i\c". This is suppose to be interpreted as "Now send everything to the screen including this newline".

The problem is that my command line prompt is "mike > ". What shows up on the screen is "ike > " and it is underlined. It is curious that the sequence "ESC [4m" is used to put the vt100 into underline mode. Have I found a bug, or am I missing something? Simon, can you hear me?

I'll probably come up with a workaround until I find what I am doing wrong. Please don't send any workarounds, but if you have the answer to how to fix the problem, I would be happy to hear it.

thanks,

mike

393. Re: Zubair Z-Ram

Newsgroup: comp.sys.atari.st.tech
Date: 1990-10-12 13:57:21 UTC
From: kentd@FtCollins.NCR.com
Message-ID: <KENTD.90Oct12145722@zappa.FtCollins.NCR.com>
Source record: 50133

> One of the nice things about the ZRAM upgrade is that the same board will
> work with any ST, as the MMU connection is on a cable.

This is not exactly true. I have two 520's, one an old STm and the other
an STfm.

In the STm the ZRAM cable is significantly too short to reach the MMU
from the shifter and even if it were the IKBD processor is right over
the shifter box and the extra height of the ZRAM board keeps the
keyboard and case from being put back together properly.

Fortunately the board fits in the STfm properly, and since thats what
the original poster inquired about he shouldn't have problems either.

Quiz: Which comes in more flavors ST motherboards or Baskin-Robbins Ice
Cream? :^)

Three other tips for all STer's wanting to do RAM upgrades:

1. Open the ST up _before_ you buy... My STfm, much to my chagrin, had
the video shifter soldered in rather than socketed. (That's why I tried it on
my old 520 first.) This meant I had to go to the extra trouble of
desoldering the shifter and putting in a new socket.

2. Another reason to open up the ST first is that some 520/1040's were
shipped with an MMU that can only address 1Mb max. I don't have the part
number memorized but if anyone is interested I can post the part number
of the "Good" MMU.

3. Zubair highly recommends Samsung DRAMs for use with their product.
They strongly discourage use of Oki, Hyundai, and Micron brand chips
because they tend to load down the power supply excessively resulting in
erratic operation.

395. Syquest hard drives

Newsgroup: comp.sys.atari.st.tech
Date: 1990-10-12 16:02:31 UTC
From: bointon@kcl-cs.UUCP
Message-ID: <1203@xenon.kcl-cs.UUCP>
Source record: 50134

Hello there!

I recently attempted to install a Syquest SQ555 removable 44m hard drive.
I was using a GE-soft host. Everything seemed to work perfectly (it's a very
nice drive) until my C drive started going flaky, beginning in the Auto folder.
Drives D and E were unharmed. This error was repeatable and consistent- Similar
effects could be induced in my other drive (seagate st157n) if the syquest was
plugged in simultaneously. The seagate works fine by itself!

I am just off to buy a Quamtum 11ms (yup that's right, 11!) 40M drive, and I'm
hoping that the two will work together.

Does anyone have any idea why or what this error could be?
The installing software could not find any bad sectors, and the DMA/SCSI
addresses seemed to be working fine. The effects were confined to drive C
whatever the order of connection or address.

Any help would be much appreciated!

397. Does anyone have the Pin-outs for 256k SIMMs?

Newsgroup: comp.sys.atari.st.tech
Date: 1990-10-13 06:47:27 UTC
From: baffoni@aludra.usc.edu
Message-ID: <12486@chaph.usc.edu>
Source record: 50137

You see, it goes like this: I have 2 meg of 256k Simms lying around
and I would love to use them. I know that there are SIMM boards available
(JRI, etc.) but I do not believe that any of them support 2 4-SIMM banks.
Someone once wrote me saying they had managed to do a direct connect with the
SIMMs, with the exception of needing to buffer, I believe, the write-enable
line. I would like to do basically the same thing, but I gotta know what
Pin(x) is and where it should go. Also, does anyone out there foresee problems
with doing this type of an upgrade? I have a 520ST (version with the rf out)
so I know that space will be tight, and that I will probably be limited to 1
meg simply because of space considerations. However, if I can do it, let me
know how.
Also, if anyone could point out a few good, easily obtainable (If I
can get it at the local bookstore, or at the campus one, this is GOOD) books
that might aid my quest for expanded memory - and the thrill of the hack!
Something like: "the TI guide to Memory" which would include total specs on
simms in-use by Macs,etc.

-Mike

Hello everyone!!!

Since there has been so much talk about hacks to perform on the
ST, I decided to send a hack I found on a BBS sometime ago to
comp.binaries.atari.st. It is supposed to increase the color palette to
32,768 color and be compatible with the JRI 4096c board and the STE. I
don't know how it works and I have not tried it yet. If someone is
willing to do it please post the results of this hack.
Also, could someone please E-mail or repost instructions on
how to add a 1.44 meg 3 1/2" drive, and I think someone mentioned that
they added two slim-line drives in the place of his standard ST drive.
Would it possible to stick two 1.44 meg drives in the place of my 720k
in my Mega? Take care!

Sincerely,

Michael Rose

The Atari ST version of Zoo by Daan Jitta can do that: "zoo a// dir"
archives the directory "dir" and recursively all its subdirectories. The
standard Zoo cannot do that. (But we have "find" under UNIX, haven't we?)

405. Re: More on Laser 2.1 vs MiNT

Newsgroup: comp.sys.atari.st.tech
Date: 1990-10-15 12:59:19 UTC
From: kentd@FtCollins.NCR.com
Message-ID: <KENTD.90Oct15135919@zappa.FtCollins.NCR.com>
Source record: 50044

Well, I figured out exactly what's happening to cause the Laser C init code to hang up MiNT. The Laser C startup module is set up to start both desk accessories as well as normal applications. The way it determines which type of program it is, is by looking at it's parent's basepage address (offset 36(decimal) into it's own)... If it's zero it starts itself up as an accessory and if it's non-zero it starts as a "normal" program.

When MiNT launches a program this location is zero and the startup code, convinced that it's a desk accessory, hangs the system.

I hacked up a prg only version of the startup code and my Laser programs now work with MiNT. The obvious long-term solution is to have MiNT put it's own basepage address in that location when it launches a program (or at least something that's nonzero). That way MiNT'll be more compatible with the programs out there that can function as both regular programs and desk accessories.

Hopefully, this change can be incorporated in the next "official" release of MiNT.

>because all versions of TOS set this up correctly,

All EXISTING versions might, but it's not documented or guaranteed.

>and lots of people use this trick to get their gem applications to work
>as both programs and DA's.

If lots of people jumped off a bridge, would that make it the bridge's fault? I'm being facetious, of course, but just because "lots of people" do something doesn't make it documented. This is called a "settled expectation," and we *do* consider them whe we make TOS changes, but it doesn't mean they're guaranteed: it's still the program's fault (in this case, Laser's startup code).

Of course, it wouldn't be hard to make MiNT start up programs with whatever key difference Laser C expects, but the fact remains that the programs are relying on something which is not guaranteed. That means they are "version dependent," and if they work under a different "version" of TOS, fine, but if they don't, blame the program, not the OS.

407. Ultradisks?

Newsgroup: comp.sys.atari.st.tech
Date: 1990-10-15 23:44:19 UTC
From: hyc@math.lsa.umich.edu
Message-ID: <1990Oct15.234419.3305@math.lsa.umich.edu>
Source record: 50047

Howdy... Anyone else out there with an Alpha Systems cartridge-port RAMdisk?

I finally figured out why I was getting trashed directories on mine... I had set up two 2 megabyte RAMdisks, and would lose the root directory sometimes. Turns out that the program passes a pre-defined BIOS Parameter Block to DOS when it asks, and always says there are only 5 sectors per FAT. Well, 5 sectors per FAT is only enough to map 1706 clusters, or 1.7Meg of space. So since the root directory begins right after the FAT, it got used up next... Lemme tell ya, ya get some bizarre looking stuff when TOS tries to interpret a root directory sector as FAT data.

I don't understand why TOS would be allowed to grab the next sector on down, since the BPB says explicitly that only X number of sectors are available, but so it went. After disassembling the Alpha Systems RAMdisk code, I found their hardcoded BPBs and changed 'em from 5 to 7, so now my RAMdisks are happy again.

Of course, now that I understand why this was a problem, (which is why I split things into 2 disks in the first place, because back when I first bought it, it only had 2 meg of RAM. I tried to make a single disk with that, and hey, it didn't work either... How silly of me to think that they would ship software set to work properly for the configuration of hardware they sold you... Sheesh.) I can merge it back into a single 4 meg partition, but now I'm more interested in just using it for cache. I get the effect anyway, for some tasks, since I have all of MWC sitting on one of the RAMdisks. But it'd be nice not to have to worry about loading specific programs onto the RAMdisk, and just let the cache program take care of commonly invoked stuff.

So... Where's a good place to start? Is CACHExxx (in the Rainbow TOS utilities) really a disk cacheing program? I had set it up to use 1000 buffers at one point, but I still saw disk activity lights trying to access a program for the second or 3rd time. This doesn't seem right to me. (For floppy access, I can understand the need to look for Media Change, but for a fixed hard drive?)

I thought I saw something about a utility being available that could
convert between standard atari graphics formats (Degas,Spectrum)
and the PBMPlus standard. If so could someone please tell me where to
get a copy.
Thanks.

409. Multisync monitors on the ST (H. Chu, where are you!!)

Newsgroup: comp.sys.atari.st.tech
Date: 1990-10-16 02:33:28 UTC
From: boyd@fsucs.cs.fsu.edu
Message-ID: <9010160233.AA06810@fsucs.cs.fsu.edu>
Source record: 50049

I have a friend that is about to invest in a multisync/omniswitch setup for his Mega4. He wishes to know what kind of multisync will be good for this. In particular, I remember a previous posting by Howard Chu about what to look for in a multisync to get a monochrome display that equals the Atari mono. I seem to remember something about dot pitch and being able to switch to a mono mode on the monitor itself. My buddy has talked to the people who sell the Omniswitch, and they recommended the Acer Multisync (which they sell, not too suprising). I am assuming that most any multi will have equal or better color rendition as the Atari Color. Anyway, any help would be appreciated. If you wish to send email, feel free and I will post a summary (maybe we could add it to the monthly posting, I see these questions come up a lot . .). Thanks in advance ;-}

410. spl or snd file format

Newsgroup: comp.sys.atari.st.tech
Date: 1990-10-16 02:45:40 UTC
From: rossj@cognos.UUCP
Message-ID: <8928@cognos.UUCP>
Source record: 50050

Does anyone know the format of .spl or .snd files? I am attempting to create samples in files, which I can play back with David Bagget's play.ttp.

My first guess was that the files are simply 8 bit data. The sounds I get out aren't very good though, so I'm wondering if there's more to the format than I know.

Thanks...

P.S. If anybody has a routine they'd like to send me or point me to, I'd really appreciate it. This is for a school project on signal processing. I'd just like to be able to hear my processed signals on the ST, where I'll be doing most of my coding.

From: swood@vela.acs.oakland.edu
Message-ID: <3406@vela.acs.oakland.edu>
Source record: 50052

I have come to notice that our school machine has a nice collection of programs for manipulating GIFs etc from within Unix/Ultrix. These include grey-scale and post script converters, as well as having converters for various mac, PC and amiga picture formats. The one that I do not see however is ST formats.

Does anyone know of sources for unix programs that will convert GIFs PICTs TIFFs and perhaps postscript to and from ST formats (DEGAS, PI1 PI2, SPU, SPC)?

Message-ID: <jlong.656090495@cassiopeia>
Source record: 50053

If I wanted to hack around with the OS on my 1040ST, what speed requirements should I look for in my E-Proms? I know that normally, people say you need 120ns DRAMS for memory expansions, but when hacking the OS, will 200ns EEPROMS work?

I had also posted a question before about upgrading to 2.5 meg using a method of replacing 16 256K DRAMS with 16 1Meg DRAMS following a text file I saw posted about 1 year ago called "A Socketed 2.5 Meg Ram Upgrade" or something like that. Has anyone had experience with this upgrade path?

Message-ID: <1990Oct16.134250.406@vax5.cit.cornell.edu>
Source record: 50054

(Forgive me if this topic has been discussed...)

For those that are STart readers, has anyone tried
to build SAMPSYN, the sound digitizer in the July,
1990 issue of STart?

If so, what was the total cost, time spent, and
what you think the ease of building is.

It sounds like a neat little spare-time project
(if I had spare time), and I was wondering if
it seems worthwhile.

Please E-mail responses, I'll post any/all info
later.

Thanks!

415. SICK 1040

Newsgroup: comp.sys.atari.st.tech
Date: 1990-10-16 18:23:32 UTC
From: jharres@sleepy.bmd.trw.com
Message-ID: <819.271aedb5@sleepy.bmd.trw.com>
Source record: 50055

My 1040 recently developed an ailment. It boots just fine but after several minutes it locks up. Hitting reset changes resolution from med to low and garbages the display. The data appears to be the original prior to the reset but in low res. A power cycle (30 sec wait) results in a white screen. After sitting for 10 to 15 minutes it will reboot leading me to believe it is a heat related problem. This was confirmed the next night when I broke out the blow drier and aimed it thru the louvers. In a minute or so it reboots and runs for hours. This worked for several evenings without new problems until last night when I popped in a different disk and hit esc. Now I had a disk directory with duplicate (completely identical) file names and other file names missing. Several esc's didn't change the display. After inseting several other disks that displayed correctly, the problem disk showed the correct contents.

Any suggestion as to what part(s) to suspect?

Jim Harres e-mail at jharres@doc.bmd.trw.com
Thanks

An excellent choice of software! :-)

>My first guess was that the files are simply 8 bit data. The sounds I
>get out aren't very good though, so I'm wondering if there's more to
>the format than I know.

The samples are 8-bit data, with no header and no tailer information.
The crucial point is that the samples are "8-bit unsigned" samples,
which means that the values correspond to voltages from 0 to +5 (so
I'm told). A value of 0 means 0V, while a value of 255 theoretically
corresponds to +5V.

This is _quite_ different from the "competing" format, 8-bit signed,
wherein each sample is taken to be a signed voltage from -2.5V to
+2.5V. To convert from unsigned to signed format you simply have to
subtract 128 from each sample. To go the other way, you add. (Sounds
simple, but try to figure it out by looking at the data files!)

Incidentally, the Hippo digitizer uses signed samples. The "standard"
ST format is 8-bit unsigned.

To convert between them, get a copy of "convert.arc" from
atari.archive.umich.edu:/atari/newitems/
The program hippo2st.ttp will convert 8bit signed to 8bit unsigned.
(Guess what st2hippo.ttp does....)

417. Atari ST emulator for the Amiga: Atari's position

Newsgroup: comp.sys.atari.st.tech
Date: 1990-10-16 23:36:53 UTC
From: apratt@atari.UUCP
Message-ID: <2710@atari.UUCP>
Source record: 50057
Cross-posted to: comp.sys.amiga,comp.sys.amiga.tech,comp.sys.atari.st.tech

Some people have expressed confusion over the legality of the "Atari emulator" now floating around the net for the Amiga. I understand that Atari's position is that it is a grave and flagrant violation of Atari's copyright, and we are asking everybody, especially archive sites and BBSes, to stop distributing it and remove all copies they have. I don't know why people think this *could* be legal: it's a derivative work from Atari's copyrighted material, and Atari intends to protect its copyrights.

Some people have expressed dismay that their favorite archive or BBS might get in trouble. In my *personal* opinion, the operators of these sites bring doom upon themselves by making uploads immediately available for downloading, with no checks on the content of the uploads. I believe that only a Common Carrier, such as the phone company or an airline, can legally be blind to the content of the information or goods they transport and distribute. Everybody else is responsible for exercising due diligence to ensure that no illegal activity is going on using their equipment or service. Since this program is prima facie a copyright violation, a duly diligent sysop would not have made it available for downloads.

Finally, some people have expressed the opinion that Atari should be a "good guy" and take no action concerning this. That's nonsense. If you don't vigorously protect your copyrights, you lose them. Ignoring this could mean relinquishing all rights to protect TOS from copying and modification.

This message represents my opinions and things I believe to be true, but it is not to be considered a legal opinion from Atari's legal department or anybody else but me.

The problem I had with my 1040stf was similar....but my installer caught it
before I got my machine back 3-days later...

It can be traced (imho) to the same problem that a few machines have had
with the Sprctre-GCR.

****** IMPORTANT ******

The two LS-373 chips on the motherboard CANT HANDLE THE EXTRA LOAD OF
CURRENT NEEDED and thus screw everything else on the power bus up.

Once these chips were (cheaply...$10/pair) replaced, the problem
went away and the machine survived a 48-hour "burn-in" with NO ERRORS.

Just some advice.

I am spending the day today making up chains of fbm1 files on unix for the various art and scanning files that I have. I am also planning on making one for converting my gif files to the most readily usable sizes and color palette for the ST. I do not have all of my reference manuals yet, and I would appreciate anyone who could send the me the pixel resolution and color limitations of a 520STfm running tos 1.1....(In know, rainbow 1.4 is my next buy)

Also, as long as I am talking graphics, are there any ways to get the older ST's modified 'all' the way (or at least most of the way) up to the newer STe's? Or do I have to start saving for a new machine?

Thanks to all how replied to my query. Here is an outline of what I think is the best solution. I implemented in Arcgsh 3.2 coming soon on comp.binaries.atari.st.

First I try to find the program's path with the shel_find() function. The parameter is the basename of the resource file. (I know at this point that the resource file exists because it has been loaded with rsrc_load() already.)

If shel_find() succeeds it returns either a full path or the filename as I handed it to shel_find. In the latter case the file is in the current directory on the current drive, and I can construct the full path myself.

If shel_find() fails I do the same as shel_find() for the directories in the PATH environment variable: PathFind() takes a filename and searches all directories in the PATH for that file. If it is found its full path is returned.

Here is a piece of source code from Arcgsh 3.2 showing the principle:

```
strcpy (buffer, "arcgsh.rsc");
if (shel_find (buffer) != 0)
{
if (buffer[1] != ':')
getpath (arcgshDirectory);
else
strcpy (arcgshDirectory, dirname (buffer));
i = strlen (arcgshDirectory) - 1;
if (arcgshDirectory[i] != '\\')
strcat (arcgshDirectory, "\\");
}
else
{
if (PathFind (buffer) != 0)
{
strcpy (arcgshDirectory, dirname (buffer));
strcat (arcgshDirectory, "\\");
}
else
*arcgshDirectory = '\0';
};
```

>can't find anything telling me how to address the DMA port for printing :-(

The DMA port is not like the parallel or serial ports. You can't just
ship a stream of ASCII characters to an Atari laser printer and expect
anything meaningful to print, for the Atari laser printer expects bit
images only. The Diablo 630 emulator, which Atari furnishes for use
with the SLM804 laser printer, works by intercepting output intended
for the parallel or serial ports (as selected by the user). It then
prepares a bitmap of the output page and ships it off to the laser
printer via the DMA port. While the emulator is active, the port that
it is intercepting is disabled.

The question you are asking, assuming you are using the emulator, is
how a C program can change the port that the emulator is intercepting.
The only way I know to do that is manually from a menu using the
"setup630.prg" program that configures the emulator, but there must be
a way to do the same thing from your own program.

In this months Amiga Format magazine there is a review of the Medusa ST emulation system. This comprises of a hardware gizzmo to emulate the STs I/O and a software emulator. From what I have seen of the review it does not fair much better than the version on xanth.

Now for the interesting part. The method of getting TOS is to go to an ST and use an included utility called gettos. This has the effect of copying the TOS from ROM into an image file. This company is about to market this product! I am quite sure they would not be so naive as to market a utility of this sort without checking the legal circumstances behind it!!!

I personally agree with what a guy said on comp.sys.atari.st concerning Apple and GNU. GNU do not port their stuff onto Apple because of the aggressive attitude they take to people emulating their products (NOT PIRACY WHICH IS QUITE DIFFERENT) and the law suits that follow. If the emulator contains an image of TOS then it is illegal. If however it is merely functionally isomorphic to the original then I personally (before the flames come rolling in this is MY opinion) congratulate the programmer on a well written piece of software.

One last twist! As a footnote in Amiga Format stated, there is a German software ST emulator coming out called Chameleon. I know nothing about this except it is meant to cost 30 pounds (=$60) whereas the Medusa hardware/software emulator costs 200 pounds (=$400). I hope the atari emulator on xanth is not the same as this reported chameleon. Things are starting to get out of hand...lock up your daughters ...call in the judges, the lawyers and the House Of Lords! Nobody is safe!!!!!!

Well thats my halfpenny !

-=Andy=-

PS the ST version of SIM City runs ok on the emulator!

>low enought, so i just removed the resistors on the drive that "pull it up".
>(It was two on my drive, one in a socket and one who was soulded on the bord)

I've done this several times, the drives are not very consistent. One even had to be exchanged because it refused to work with the ST. Basically the procedure I used was such:

1) remove the resistor pack from the socket on the rear of the drive and see if the drive works like this. Some drives work fine this way.

2) use 330-ohm resitors (low wattage to avoid damaging the socket) between opposite holes in the socket and experiment to determine which resistors of the 8-pack are needed so that disks can be formatted 40 tracks, read and written properly. Different drives needed different combinations.

3) bend out the pins on one side of the resistors which cause trouble and make sure of leaving in the ones that are necessary.

When I rewired my ST so that both drive select lines were taken out to the ST's external diskdrive connector, A: as DS0 and B: as DS1 a drive which didn't need any resistors wouldn't work without them and a drive which did need them wouldn't work with them. Some of the signals seem to be a bit flakey if rerouting a couple of wires can make this difference.

Hope this helps.

430. Making timer-based interrupts work

Newsgroup: comp.sys.atari.st.tech
Date: 1990-10-18 04:18:42 UTC
From: jpexg@ai.mit.edu
Message-ID: <11428@life.ai.mit.edu>
Source record: 50069

I'd very much like the ability to write interrupt routines in Laser C which could be set up to occur at a given frequency while a program runs. A block of C code would execute, and then control would return to wherever it jumped from. Obviously, such a function wouldn't be able to use arguments or return anything, but it could operate on global variables.

Assembly language fragments are fine, but I'm not an assembly programmer. If anyone has written something that works, I'd like to try it.

John Purbrick

Nope. As I understand it, the GNU issue had _nothing_ to do with emulation.
It was a result of Apple's look-and-feel bull regarding the appearance
of competing products such as MS Windows, HP New Wave, and earlier, GEM.
Apple _popularized_ the use of a mouse and windows, but did not _invent_ it.

Although the Free Software Foundation (creators of GNU and the associated
utilities) do not claim a copyright to their work (in fact, they have a
"copyleft"), they do not oppose others protecting their work. Apple
has not bothered those who market Macintosh emulators based on legal copies
of their ROMs.

I think it was perfectly obvious from Eric Smith's posting: the "value"
part of the zero cookie contains the size of the cookie jar, in cookies.
Multiply by 8 for the size of the cookie jar in bytes. This is regardless
of how many slots are actually USED. To install a cookie into a
cookie jar which has one or more slots available, you move the zero cookie
down one, and put your new cookie in just before it. You don't change
the value of the zero cookie, because you didn't change the size of
the cookie jar.

>Nope. As I understand it, the GNU issue had _nothing_ to do with emulation.

Emulating as in "copying the look and feel," I'd imagine. Certainly, Gnu does
believe in free software (free from restrictions, not free in price), but
their beef with Apple is that they have tried to keep other people from using
the GUI concept at all, not that they have tried to keep people from
pirating their own software. Most Gnu stuff is reverse-engineered from Unix
tools, but none of it is stolen. If (to give a hardware example) Atari
decided to run off and sue any micro supplier who sold PCs with a MIDI
port built-in (an original selling point for the ST), the FSF might get
upset.

Atari has a right to protect its software, just like Apple does. I like
free software and free movies, but I don't get upset because Cineplex
keeps me from sneaking in.

Regarding this entire thread of messages...Does it really matter what
Atari's position is about the emulator? Whether the emulator is illegal
or not doesn't change the fact that there are thousands of potential
users of the emulator, and since there is no DEFINITIVE proof that it is
illegal, those same users will most likely feel no guilt in using the
emulator. As far as I am concerned, the program is a novelty, something to
show you "ST friends" when they start bad-mouthing the Amiga. As far as
usefullness: Why do Amiga users want to emulate an ST? There is NOTHING the
ST can do that the Amiga can't do hundreds of times better. That's why you
bought the Amiga, right?

Atari's position on this matter is correct. Although it may be considered flattering for someone to emulate an ST on an Amiga (with all the "mine is better than yours" type arguments around), the software copyright position is clear - that software is illegal.

If you wrote a commercial piece of software and someone, without your permission, ported this software to another machine would you not be phoning your lawyer the instance you discovered it? Even worse, if your software wasn't even ported - just binary copied and the target machine hacked a bit so your software would work...

Whether or not there is a potential for loss of profit is not really the issue. The issue is software copyright which is being breached. End of story.

Dave.

Hello Daniel!

Rainbow 1.4 is another name for the version 1.4 of TOS. You can get the new ROM's from your local Atari dealer.

Greetings, Olaf

You may be thinking of a set of programs I wrote and submitted to comp.sources.misc with the collective name "ataritoppm". You should be able to dig them up if you can find a site that archives c.s.misc, otherwise I'd be happy to email them to you.

Here's the announcement I posted to comp.sys.atari.st a few months ago:

In case anyone is interested, I've just submitted the following programs to comp.sources.misc. They convert between two Atari image file formats and Jef Poskanzer's pbmplus format:

pi1toppm.c -- Reads low-resolution Degas and writes ppm
ppmtopi1.c -- Reads ppm and writes low-resolution Degas
spctoppm.c -- Reads compressed Spectrum 512 and writes ppm
sputoppm.c -- Reads uncompressed Spectrum 512 and writes ppm
ppmtospu.c -- Reads ppm and writes uncompressed Spectrum 512

I wrote these originally on an Amiga (don't shoot!). They should compile just fine on any Un*x platform. I haven't used C on the ST for a while, but I imagine they should compile easily enough.

If you are unfamiliar with pbmplus, it is a wonderful graphics manipulation package, written by Jef Poskanzer, which, in addition to being able to read and write many different image formats, can perform many useful manipulations such as scaling, rotation, etc. For more information on pbmplus, check the frequently-asked questions article in comp.graphics.

447. Need help with hard drive (URGENT)

Newsgroup: comp.sys.atari.st.tech
Date: 1990-10-20 04:14:57 UTC
From: david@doe.utoronto.ca
Message-ID: <1990Oct20.041457.18263@doe.utoronto.ca>
Source record: 50087

I bought a new ICD 85-meg hard drive today. I changed the SCSI device number on the back to '1' (my megafile 30 is '0') and hooked it up. Unfortunately, the hard drive still thought that it was device '0'. By the time I realised this, I had badly damaged information on my megafile 30, _including_ several weeks' work on the English translation for the new Calamus SL manual.

My megafile had 3 partitions, C:, D: and E:. C: is pretty trashed (the FAT is in bad shape), but that's OK. E: is fine, but it shows up as D:, and D: is missing altogether. When I use hdx, it knows that there are three partitions on the drive, but the (former) D: partition seems to be invisible to GEMDOS. That's where I have the Calamus manual which I (foolishly) did not back up to floppy.

Please, how do I get GEM/GEMDOS/BIOS to recognise the partition? This is a fairly serious emergency, and I would appreciate any and all help. Please respond by mail as soon as possible, and I will summarise to the net. Thank you.

Controlling the RS232 port from GFA Basic. An actual example.

Void Xbios(15,7,0,&H88,1,1,-1) ! RS232 configuration/baud rate. (See below.)

>scr: Some sort of syncronous data i/o port.

Actually this is a register to hold the "sync" character for syncronous serial I/O. This character is sent automatically at the beginning of each data transmission, and is used by the receiver to synchronize with the recieved data.

In asynchonous modes this is not used (the start bit performs this function instead, but needs to appear on each byte. You only need one "sync" character per data block and a block might have thousands of characters)

Of course in synchronous mode you also need to send a clock with the data and in asynchronous mode no clock is needed

450. Missing partition on HD (part 2)

Newsgroup: comp.sys.atari.st.tech
Date: 1990-10-20 15:52:03 UTC
From: david@doe.utoronto.ca
Message-ID: <1990Oct20.155203.4378@doe.utoronto.ca>
Source record: 50090

I recently posted about my hard drive woes, especially the magic vanishing partition which (holds? held?) about 60 pages of the English translation of a new Calamus manual.

The partition still exists, and its statistics (size, etc.) are correct. However, GEMDOS/BIOS will not read it, because its type has been mutated to EEM instead of GEM!

How can I change the partition sector without wiping the whole partition? If I can get it back to GEM, I might be able to recover some files before I redo the partition. All help appreciated. Thanks.

451. Hard Drive interferring w Mono Monitor. Solution Sought

Newsgroup: comp.sys.atari.st.tech
Date: 1990-10-21 06:14:00 UTC
From: moses@hao.ucar.edu
Message-ID: <8905@ncar.ucar.edu>
Source record: 49991

A fellow in our user group has a very unusual problem involving
his new external hard drive and his monochrome monitor.

The PROBLEM:
Copying of some files to or from his hard disk drive causes the
vertical sync on his monochrome monitor to be lost.

The CONDITIONS are:

- Latest ICD host adapter and booter.
- Seagate ST177N drive.
- Any ST computer (we tested a couple).
- Only Monochrome monitors (we tested 3 monos). Problem does
not exist when a color monitor is connected.

The files that are copied to/from the hard drive and cause the
vertical sync to be lost are successfully copied (even successive
files in a multiple copy). The files that cause the problem have
nothing in common; for example, one file is a desk accessory and
another is a resource file to a different program. These 'problem
files' (the problem is not the files but something to do with the
hardware) will cause the vertical sync on the mono monitor to be
lost everytime. With one file we were able to isolate a particular
block of the file as the culprit by saving the block as a new file.

Has anyone experienced this problem before? Does anyone have an
solution to the problem?

A technically inclined fellow in our ST community has been conferred
and he thinks that somehow these problem files have a bit pattern in
them that when transfered into or out of the hard drive create
interference with the vertical sync of a monochrome monitor.

The poor guy with this problem has lost 2 months getting his new
hard drive mechanism working. He has shipped it back and forth
twice now. There was one other problem with this external hard drive
system that was finally solved by replacement but this remaining
problem is something really unusual indeed.

Is there:

1. A TOS type more program with the same look and feel (and most of
the functions!) of the unix binary 'more'?

2. Is there any way to replace the more in Gulam with it?

I am a vi-guy, and do not like the emacs clone that Gulam uses for it's more
function. Please include a filename and ftp site (if applicable). Thanks
in advance!!

Message-ID: <1990Oct21.154411.18598@doe.utoronto.ca>
Source record: 49993

Thank you to all those who helped me save my hard drive partition.
What I had to do was edit sector 0 of the physical drive and change
the partition type from EEM back to GEM. There was minor FAT damage,
but I retrieved all of my important files onto floppy.

To edit physical sector 0, I had a friend and registered developer
use her/his (sorry, Atari, no hints as to the person's identity)
CHKDISK3 program to change the partition type.

I am still having problems. The Megafile 30 is SCSI device 1 (LUN 0),
and the FAST 85 meg ICD drive is SCSI device 0. I am having EXTREME
problems writing to or reading from the megafile 30 (more than about
10 bytes, and there is corruption). It works fine hooked directly to
the computer, but poorly chained through the ICD drive. Do I need
to use shorted DMA cables?

forget more...use less.ttp. it allows you to scroll backwards which is a huge gain over more. you can probably find it at atari.archives.umich.edu. the latest version is v97, though i do remember v123 posted quite some time ago in alt.sources (beta). in fact, you can modify your desktop.inf to use less as the pager for the desktop itself.

> 2. Is there any way to replace the more in Gulam with it?

i generally alias "t" to "less" and just type "t filename" which is faster than "more filename". i believe that aliases take precedence over built-ins so aliasing more to c:\bin\more.ttp (or whatever) will probably work. "t" stands for "type" (ala MS-DOS and VMS, though i don't use either much if at all, prefering unix look/feel and correct byte order in words :-).

>I am a vi-guy, and do not like the emacs clone that Gulam uses for it's more

too bad, that's your loss... *8^)

actually, i don't like the gulam emacs clone either. there are superior alternatives: 1) MicroEMACS (i use v3.9i over v3.10), 2) a port of real GNU emacs (which is big and somewhat flakey in a "normal" CR-LF TOS environment). the former loads in about a second from a ramdisk, so there is no real speed improvement of gulam emacs. gulam emacs does let you fg/bg the editor, though, which is nice. there are other emacses (jove, MWC emacs, micrognuemacs, etc), but i think (for me) MicroEMACS is the best all around. language context sensitivity and multiple windows make emacs superior for me. and the argument for portability of vi over emacs is waning: emacs is supplied/available by/for most (unix) vendors these days including convex, cray (soon?), sun, dec, AIX (?), etc, etc, etc).

Source record: 49995

Maybe some one out there can help me on this.

How do these STDMA to SCSI adapter boards really work. I have seen a few
and it all looks so trivial but without any info on the ST DMA port I cannot
work out how its all done. The best that I have seen so far are the BMS200
which really does seem to support the full (well almost) SCSI (I) command
set and the new ICD adapter which is so small, you plug it onto the back
of a SCSI drive. These two boards don't have all that much on board. So
if its legally possible to disclose such info (which iI think it is) could
some kind soul kindly enlighten me as to what is actually done. I would like
to try it as a hardware project and hopefully get somewhere.

Thanks in advance.

Source record: 49997

I have that GE-Soft host-adapter and I am planning to install an another drive to keep company for my Seagate ST296N.
How? Get a 50 lead flat and connectors or just a connector and press it in between the host-adapter and the existing drive, if you have room in the housing for second drive (do you have GE-Megadrive?).
If there is no room, connect that flat to the host-adapter and the drive.
Yes, it works! My drive is the M-Drive by Digital-Systems, using the same host-adapter type as GE.
Did you remember to set the SCSI device number of the second drive.
Can be from 0 to 7. So, you have 8 DMA devices possible, each of them can be a host adapter. To a host-adapter you can connect up to 8 SCSI devices.
Total of 64 HDs! Thinking about 64x1200 Mb CDC, 9 ms...

Well, I hear the mouse offering by Konyo is essentially a Microsoft mouse, and the MS mice are very durable (can anyone confirm/deny the Konyo=MS mouse statement?). You could also hack a Microsoft Mouse (bus version) to work with the ST. I intend to do this if my ST one ever dies. If you did not know, the Atari mouse design changed (at least) once, the new one has nice big teflon sleeves on the rollers. I have one of these, and it has worked great for over 2 years (of HEAVY use).

>checking all the ROMs and RAMs are sitting there firmly.....

Yes, I also think that you have problems with your ROM sockets,
because Atari has used the cheapest available sockets ("power without
the price"). But you can test whether the ST bombs because of bad
contact. If you boot with a RAM TOS from disk the ST must not bomb.

Fixing the ROMs properly is only a quick solution to this problem.
If you often move your ST, the bombs will return. It is better to
exchange the cheap sockets for high quality sockets. I have done this
on my ST, because I had the same problems, and the ST works fine up to
now.

463. Re: Hard Drive interferring w Mono Monitor. Solution Sought

Newsgroup: comp.sys.atari.st.tech
Date: 1990-10-26 19:32:17 UTC
From: tdrga@walt.cc.utexas.edu
Message-ID: <38754@ut-emx.uucp>
Source record: 50003

I have had my Toadfile 44 removable hard drive for about a month now, and
I have noticed the interference problem on many occasions.

Here is a typical session that results in the interference: (from memory)

1. I have an ARC, ZOO, or LZH'd file on drive G:

2. I run the respective un-archiving program...

3. About 50% of the time, sometime during the time the files are being un-
archived, I hear a 'pop' from my 1040 stf and the monitor goes bonkers.

4. The un-archiving continues and finishes with no problem (unless I turn
off the computer).

The hypothesis posted earlier that it had something to do with sequential
reads/writes and the ICD adapter sounds like what is happening. I have not
opened up my Toadfile, but I assume it has the latest ICD adapter as of the
date it was shipped. Other than this, my drive has performed perfectly.

The problem seems to be the horizontal sync on the mono monitor. This is
_my_ guess... it just looks like tthat to me based upon my experience, I
have not attempted to trace it and can't say exactly...

The interference has also occurred on one occasion when I copied many files
from my floppy to the HD.

Anyone know of a fix for this? Has anyone heard from ICD on this?

oh, BTW, my setup is a stock 1040stf, the HD, color and mono monitors,
printer, and modem.

E-mail for more info if you need it...

Thanks,
Todd

Source record: 50005

Both of my hard drives, the ICD F.A.S.T. 85 and the Megafile 30,
have finally learned to live together in peace, harmony and
sibdom (brother/sisterhood).

Now, how should I set up caching for the best effect under TOS 1.4?
I have turned off write caching in the ICDBOOT driver (it scares
the dung out of me), but I have to choose among using only
Atari's CACHEnnn.PRG (which is _very_ fast), ICDBOOT's built-in
read caching, or some combination of the two. Any suggestions? Is
CACHEnnn.PRG safe to use with ICDBOOT, or does it need AHDI?

This question is probably of enough general interest to warrant
replies directly to the net. Thanks.

Hello David!

CACHEnnn.PRG from Atari increases the number of disk-buffers which will be used by GEMDOS to cache the FAT- and DATA-sectors (including the directory-sectors). I don't know the ICD-driver, but I think it will cache the HD-sectors internally, so if you use CACHEnnn.PRG and the cache in the ICD-driver you wast only memory. The search-algorithm for cached-sectors is very good in TOS 1.4, so I prefered it.

Greetings, Olaf

I have just found a bug in sozobon top:-

If dlibs is compiled with the -O flag then the library becomes completely broken

If sprintf.c is compiled with cc -S -O sprintf.c then the following code is produced:-

```
_sputc:
link a6,#0
move.l 10(a6),a0
move.l (a0),a0
addq.l #1,(a0)
move.b 9(a0),d0
move.b d0,(a0)
ext.w d0
unlk a6
rts
```

If compiled without the optimiser switch then the following code is produced:-

```
_sputc:
link a6,#0
move.l 10(a6),a0
move.l (a0),d0
addq.l #1,(a0)
move.l d0,a0
move.b 9(a6),(a0)
move.b (a0),d0
ext.w d0
unlk a6
rts
```

Is there a fix for this bug. (I wont fix(I'm not an expert at C))

Luke.

469. WANTED: Hardware specs

Newsgroup: comp.sys.atari.st.tech
Date: 1990-10-29 12:04:22 UTC
From: J.Derrick@newcastle.ac.uk
Message-ID: <1990Oct29.120422.21737@newcastle.ac.uk>
Source record: 50015
Cross-posted to: comp.sys.atari.st.tech,comp.periphs.scsi,comp.periphs

Has any kind soul out there got details/know of a ftp site with hardware
details for any of the following:

Shugart floppy drive connections [are datalines TTL? {for muxing}]
Details of high density drives [to design a interface for the STe]
SCSI hard drive connections

PC keyboard for the ST [I heard of this ages ago- anyone know?]
STe alog joysticks/lightpen [no joy even after tracing the board!]

Also I'm after an inexpensive SCSI harddrive to go with a ICD host adapter
[about 60Mb ->ST177N?] -anyone got a dusty mac they don't want anymore... :-)

I'm currently converting my STe to a Towercase with a harddrive and switches
for booting, extra drives, reset, drive track monitor, coffee machine
controller, etc and would find these details very usefull.

BTW, tower case conversions are quite easy [I'm addicted to the smell of
burning solder flux!]. Get a case and recover half of your desk!

Thanks in advance,
James.

You can combine all those caching mechanisms without danger for your
data. CACHEnnn is no separate cache program; it just extends
GEMDOS' internal sector buffer list. This won't collide with any
external caching by hard disk drivers etc. (if properly done, of
course).

I would like to know if anyone knows if DC Sea is not workable on the STE,
My father just got an ste because his 520 died. And he is not able to run
the self-extracting archive on his start disks on his ste. He brought them
to my house and I was able to run them? Is there a known problem with
DC Sea and the ste? Also, if there is a known problem, is there any way to
patch the arcs to be un-arcable on the ste, or is there a version of arc
that will unarc these files.....????

From: moses@hao.ucar.edu
Message-ID: <8978@ncar.ucar.edu>
Source record: 50013

I have a program in which one of the dialogue boxes are handled without using form_do(). Yes, form_do() is the easiest way to handle dialogue boxes but I am doing some trickier things than what form_do() can handle.

Problem - If I depress the mouse button outside the dialogue box which is being handled without form_do() and atop the slider bars, or GEM dropdowns (anything GEM itself is taking care of through evnt_messages), it locks up the program completely; only the mouse can move yet do nothing.

Ques. -How is it I can disable GEM so that this will be prevented while I am using this dialogue box?

Thanks,

J.Moses

david@doe.utoronto.ca (David Megginson) asks:
|
| Now, how should I set up caching for the best effect under TOS 1.4?
| I have turned off write caching in the ICDBOOT driver (it scares
| the dung out of me), but I have to choose among using only
| Atari's CACHEnnn.PRG (which is _very_ fast), ICDBOOT's built-in
| read caching, or some combination of the two. Any suggestions? Is
| CACHEnnn.PRG safe to use with ICDBOOT, or does it need AHDI?
|

Good questions! It will be interesting to hear what folks have to say.

I use a cache mostly to speed up compiles, so that's how I test a cache.
Otherwise, I'm not an expert on this topic, so if I make some erroneous
statements, take it easy, ok?

I find the ICDBOOT built-in cache, Atari's CACHEnnn, and the cache included
with DiamondBack 2.xx to be roughly equivalent in performance for compiling. I
understand that DiamondBack has special hooks into it's cache that allows for
faster backups than could be obtained with the other caches. I haven't tested
this. I only use the DiamondBack cache now, because it's desk accessory
allows for the most convenient adjustments to the configuration, and because
I can always be ready for a quick back-up. Also, the desk acc maintains
some statistics so it is easier to optimize the configuration. I also
like the fact that I can pick which drives will be cached. ICD's and Atari's
caches will cache everything - including a RAM disk, which is pointless.

The spec sheet for the WD1770/1772 floppy controller, which is used in the ST, says the 8-bit databus is capable of driving 1 standard TTL load or 3 LS loads.

> Details of high density drives [to design a interface for the STe]

High density floppy drives can be driven directly, merely by replacing the 8MHz clock feeding the WD1772 with a 16MHz clock. Note that the WD1772 chips are only spec'd for up to 10MHz operation, so this isn't a sure-fire solution. I don't know what kind of replacement controller is supplied with, say, the PowerDrive kit. Btw, I see in Computer Shopper that 2.88MB floppy drives are now available for around $150 each. Given the average price of 1.44MB drives at around $65-90, that's not too bad. If I knew enough about these I'd consider sticking one of 'em in...

> SCSI hard drive connections

Read the comp.periphs.scsi newsgroup. They're full of SCSI info, and can also point you to archives with the full SCSI spec and lots of other stuff.

> PC keyboard for the ST [I heard of this ages ago- anyone know?]

Bleah. PC keyboards are disgusting. (Oh, sorry. "IMHO". }-)

> STe alog joysticks/lightpen [no joy even after tracing the board!]

Dunno, have you tried just plugging in, say, Apple or PC analog sticks?

>Also I'm after an inexpensive SCSI harddrive to go with a ICD host adapter
>[about 60Mb ->ST177N?] -anyone got a dusty mac they don't want anymore... :-)

Lessee... In Computer Shopper I see that a 60MB ST177N, bare, is $349. Not bad. 20ms access, also not bad. I just ordered a Syquest (44MB cartridge) drive for $530. Slower, and more expensive to start, but I figure it'll be a win by the time I buy my second cartridge. (Heck. The atari.archive stuff won't even fit onto 1 cartridge now. Guess I should've ordered extra carts at the outset... }-)

>I'm currently converting my STe to a Towercase with a harddrive and switches
>for booting, extra drives, reset, drive track monitor, coffee machine
>controller, etc and would find these details very usefull.

Coffee machine controller?? Geeze..... }-) Can't you get that sort of
functionality using a BSR-X10 Powerhouse controller?

>BTW, tower case conversions are quite easy [I'm addicted to the smell of
>burning solder flux!]. Get a case and recover half of your desk!

Sounds cool. Got any notes you could share?

475. Re: Bug in sozobon top

Newsgroup: comp.sys.atari.st.tech
Date: 1990-10-30 02:03:30 UTC
From: nisimura@srava.sra.co.jp
Message-ID: <4730@srava.sra.co.jp>
Source record: 50010

In article <5940@harrier.ukc.ac.uk>, L.R.Henry writes;

I have just found a bug in sozobon top:-

If dlibs is compiled with the -O flag then the library becomes completely broken
If sprintf.c is compiled with cc -S -O sprintf.c then the following code is
produced:-
....

Do you use top v1.20, don't you ?
top v1.20 sometimes does his work under erroneus conditions.
When I got Sozobon v1.2 and recompiled my programs, I encountered the
same top's bug.

Is there a fix for this bug. (I wont fix(I'm not an expert at C))
....

Yes, I have it. I looked the output of top v1.20 closely, which was
more improved than top v1.01. Next, I inspected source codes of top,
and I found that there was room for more optimizations as well as its
bug.

I modified peephole optimization routines extensively. My personal
version top, namely v1.2x is currently stable, can produce an
(quite a bit) smaller/faster executables, and is free from the
above-mentioned bug.

I enclose a change note at the tail of this article.
Caution: the version is not official.

Other bugs:
In the course of my hack, I found other bugs of SozobonC. First,
jas generates incorrect codes for bit instructions: bchg, bclr, bset, btst
It is well-known bug. And, some routines in dlib1.2 have coding errors.
bzero.s has two errors, and memcpy.s does one.

```
============================================================
Sozobon Optimizer v1.2x Change Notes
-- Oct 1, 1990 by Tohru NISHIMURA, SRA Inc., Tokyo
============================================================
```

This notes describes modifications about Sozobon Optimizer "top" v1.2x.

o General
Peep hole optimization is modified extensively.
a. chances to optimize are extended.
b. cases which seldom happen were deleted.
c. orders of case analysis were changed for fast decisions.
d. case analysis bugs were fixed.
e. "address register indirect with index" addressing mode
is used as much as possible.

o Problems & Fixes
1. top v1.20 sometimes does his work under unnecessary conditions.

=> Just a case analysis error: fixed.

2. Sozobon Compiler, "hcc", is too innocent about effective address
calculation scheme, especially for an element of structure array.
Array reference is done as follows;

a. calculate index
b. extend the value to long (with/without sign-extent)
c. add base address
d. move the result to one address register
e. make a reference using either register indirect mode or register
indirect with displacement mode.

This procedure is simplified with a MC68000 versatile addressing mode;
"address register indirect with index" mode. With this mode,
a reference to an element of struct array is done intuitionally.

top v1.2x uses the addressing mode as much as possible.
In best case, the optimizing effort saves 2 words space and a few
clocks for each instance. In worst case, it results in just an
exchange of operands between two instructions.

3. top v1.20 sometimes fails to optimize in spite of that it is
coded to do.

=> Some are due to case analysis error, others due to Sozobon C
convention. Former was fixed, latter not.

Description of latter problem: d0 register is used for returning
function result. top v1.20 blindly assumes that rts/rtd/rte
instructions refer to sp and d0, even if the function type is
void. This infers top's optimizing procedure. If a function
actually returns a value, there is no problem. Because value
assignment to d0 register is always preceding to rts/rtd/rte
(that is, d0 becomes "dead" near at the end of function),
thus intermediate d0 can be subject to optimize for top.
If the function returns no value, top would think d0 register is
being alive until the end of function. In this case, every
d0-relating optimization instances just preceding to rts/rtd/rte
will fail to work. To solve this problem completely, hcc must be
modified.

o Open problems

1. hcc should use "address register indirect with index" mode
for oneself. The efforts of top v1.2x will not work well in some
cases.

2. hcc does not utilize contents of registers at all. Effective
addresses are calculated on every instances, even if the same
value is alive in registers. This approach simplifies hcc,
but the elimination of common expressions should be done in
compiler, rather than optimizer.

3. code reduction with bit instruction; some code sequences can be
optimized using bit instructions, btst, bset.
For example,
if ((x & (1 << y)) == 0) ...
x |= (1 << y);
bit instructions cannot be used via C language directly, this kind of
optimization may be actually what optimizers should do.

4. register a2 and d2 are never used for any purpose. They may be
reserved for scratch registers, but I have never seen hcc used them.
top does not utilize them for "registerising".

--- end of change ---

476. SCSI Device ID#

Newsgroup: comp.sys.atari.st.tech
Date: 1990-10-30 05:45:49 UTC
From: paulm@ccicpg.UUCP
Message-ID: <786@ccicpg.UUCP>
Source record: 50014
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

I am currently writing a driver for my scsi cartridge tape drive.
I have it working doing tar's and other stuff as Device ID# 0 but
I want it to work with my hard disk pluged in also. I have written
a lot of disk code in assembler based on some code from an Abacas
book but I can't get it to talk to anything but ID 0. Is the BMS100
capable of talking to other IDs (preferably #6) ?

If and when I get this working I'll release my code here as PD.
Any help would be apreciated.

Here is a little code segment:

```
scsi_read:
movea.l #$ffff8604,a0 ; WDC
st $043e ; flock
[....] ; move the buffer address in 3 DMA addrs
move.w #$88,2(a0) ;

lea CDB,a2 ; get CDB pointer
clr.l d0 ;
move.w #5,d1 ; CDB size

10$: move.b (a2)+,d0 ; get CDB byte
swap d0 ; put it in upper 16 bits
move.w #$8a,d0 ; get ?
move.l d0,(a0) ; write it to WDC
brs short_wait ; short wait for intr
dbf d1,10$ ; loop for 6 CDB bytes

......
```

The code was from memory so probably is not very correct but hopefully
it will give you some idea on where I need to work on this for the ID.

Well, Thanx in advance, Paul Moreau.

Use wind_update(BEG_UPDATE) and wind_update(END_UPDATE) to prevent
the AES screen manager from taking care of menus and the like while
you are doing your dialog tricks on the screen. This hint is valid
for any situation where you are doing something on the screen (VDI
calls, but objc_change() calls also).

478. Homebrew SIMM expansion.

Newsgroup: comp.sys.atari.st.tech
Date: 1990-10-30 12:43:51 UTC
From: tmp@doc.ic.ac.uk
Message-ID: <2408@gould.doc.ic.ac.uk>
Source record: 50017

In my never ending quest for memory (without the price :^) I tried a simple experiment on my ST.

What I did was to remove the 8 highest bits from bank 1 in my ST and wire up a SIMM socket so that the corresponding data, address, cas, ras & write lines went to those which the 41256's had occupied.
I triple checked this, plugged a 256k SIMM into the socket, powered up and... BINGO!! the ST couldn't see the top bank.

I plugged the original 41256s back and then powered up to find that the top bank was there again.
The SIMM was a 256k * 8 150nS (the original 41256s are 150nS).

I was hoping to find that this works, so that I could wire it all up and buy some 1M SIMMs to plug in (with A9 wired up of course).

As I understand it, the SIMM should be equivalent to the 8 41256s, except that the address, cas, ras & write lines are tied in parallel. I kept the wires as short as possible etc, so I don't think that this was the problem.

Does anyone else have any experience with this - or any suggestions why it didn't work?

481. Re: Hard Drive interferring w Mono Monitor. Solution Sought

Newsgroup: comp.sys.atari.st.tech
Date: 1990-10-30 19:14:11 UTC
From: steveg@com.com
Message-ID: <STEVEG.90Oct30141411@narnia.com.com>
Source record: 50019

I had a similar problem with my Mega 4 and my mono monitor.
Color worked fine, but accessing either of my hard drives
(a Seagate 277N and a Syquest 44meg cart) with my *NEW*
ICD Advantage ST (no plus) adapter would make the mono monitor
APPEAR to lose both horizontal and vertical sync. I played around
with the monitor adjustments and was able to stabilize vertical
hold for both normal and "Weird" mode, but the horizontal display
was still flaked out - seems like there were the right number of
black and white dots per scan line, but they were garbled.

Anyway, the nice guys at ICD suggested I check my adapter for
a daughterboad with two blue capacitors underneath it. Sure
enough they were there. Clipping BOTH of them off improved the
situation, but not completely. Replacing the ICD (long) DMA cable
with a short (Atari size) cable seems to have done the trick for
me. Before you start mucking with your host adapter, try a short
DMA cable as I'm not sure if removing the caps was really necessary.

From: newton@ils.nwu.edu
Message-ID: <2380@anaxagoras.ils.nwu.edu>
Source record: 50020

Hate to be dumb, but, apparently having lost a number of reference notes and stuff in a move, I'd like to know the following:

How do you do a ISR on an ST (i.e. replacing the serial interrupt handler for AUX:)? What trap does this? (I assume/vaguely recall it was a trap anyway)
What vector is currently used for the RS232 receive/transmit interrupts? Or how do I get it?

Obviously, I'm doing some serial stuff, but I'm way lost for some reason, probably lack of time and info. And don't tell me to buy ST internals, I have no money.

Hm. With sufficient memory and a good cache, isn't the whole idea of a
RAMdisk pointless?

I'm hearing conflicting info on Atari's CACHENNN.PRG. Does it only cache
FAT and directory info, or also data sectors? The behavior appears a little
erratic to me, showing disk hits when I wouldn't expect any to occur...

============================================================
Sozobon Optimizer v1.2x Change Notes
-- Oct 1, 1990 by Tohru NISHIMURA, SRA Inc., Tokyo
============================================================

This notes describes modifications about Sozobon Optimizer "top" v1.2x.

o General
Peep hole optimization is modified extensively.
a. chances to optimize were extended.
b. cases which seldom happen were deleted.
c. orders of case analysis were changed for fast decisions.
d. case analysis bugs were fixed.
e. "address register indirect with index" addressing mode
is used as much as possible.
```

o Problems & Fixes
1. top v1.20 sometimes does his work under unnecessary conditions.

=> Just a case analysis error: fixed.

2. Sozobon Compiler, "hcc", is too innocent about effective address
calculation scheme, especially for an element of structure array.
Array reference is done as follows;

a. calculate index
b. extend the value to long (with/without sign-extent)
c. add base address
d. move the result to one address register
e. make a reference using either register indirect mode or register
indirect with displacement mode.

This procedure is simplified with a MC68000 versatile addressing mode;
"address register indirect with index" mode. With this mode,
a reference to an element of struct array is done intuitionally.

top v1.2x uses the addressing mode as much as possible.
In best case, the optimizing effort saves 2 words space and a few
clocks for each instance. In worst case, it results in just an
exchange of operands between two instructions.

3. top v1.20 sometimes fails to optimize in spite of that it is
coded to do.

=> Some are due to case analysis error, others due to Sozobon C
convention. Former was fixed, latter not.

Description of latter problem: d0 register is used for returning
function result. top v1.20 blindly assumes that rts/rtd/rte
instructions refer to sp and d0, even if the function type is
void. This infers top's optimizing procedure. If a function
actually returns a value, there is no problem. Because value
assignment to d0 register is always preceding to rts/rtd/rte
(that is, d0 becomes "dead" near at the end of function),
thus intermediate d0 can be subject to optimize for top.
If the function returns no value, top would think d0 register is
being alive until the end of function. In this case, every
d0-relating optimization instances just preceding to rts/rtd/rte
will fail to work. To solve this problem completely, hcc must be
modified.

o Open problems

1. hcc should use "address register indirect with index" mode
for oneself. The efforts of top v1.2x will not work well in some
cases.

2. hcc does not utilize contents of registers at all. Effective
addresses are calculated on every instances, even if the same
value is alive in registers. This approach simplifies hcc,
but the elimination of common expressions should be done in

```
compiler, rather than optimizer.

3. code reduction with bit instruction; some code sequences can be
optimized using bit instructions, btst, bset.
For example,
if ((x & (1 << y)) == 0) ...
x |= (1 << y);
bit instructions cannot be used via C language directly, this kind of
optimization may be actually what optimizers should do.

4. register a2 and d2 are never used for any purpose. They may be
reserved for scratch registers, but I have never seen hcc used them.
top does not utilize them for "registerising".

485. Internal drive replacement

Newsgroup: comp.sys.atari.st.tech
Date: 1990-10-31 06:15:55 UTC
From: ekrimen@ecst.csuchico.edu
Message-ID: <1990Oct31.061555.5232@ecst.csuchico.edu>
Source record: 50023

A friend of mine needs to replace his internal drive on his 1040.
Which drives are best to use? Thanks!

486. More on multisyncs

Newsgroup: comp.sys.atari.st.tech
Date: 1990-10-31 06:20:28 UTC
From: ekrimen@ecst.csuchico.edu
Message-ID: <1990Oct31.062028.5300@ecst.csuchico.edu>
Source record: 50024

I'm back on the hunt for multisyncs. Here's more info on the Wuztek. If anyone sees any deficiencies in the specs, I'd like to know. Moreover, Paul, the technician I talked to at Wuztek, said that LeRoy Valley for ST Informer and Greg (missed his last name) from STart are doing reviews on this monitor; the STI article should be published in the next issue. Paul said that they use a Japanese monitor that a lot of OEMs, like Unisys, use.

Here are the specs for the Omnimon Rainbow:

Picture tube: 14 inch, dark-tint, non-glare, 0.31mm dot pitch, 90 degree deflection 55% transmission
Resolution: Maximum 1024x768 dots
Display colors : TTL: 64/16/8/4
Analog: unlimited
Scanning frequency: vertical: 45Hz to 90Hz
Horizontal: 15Khz to 36Khz
Display area: 245mm x 180mm
Power input: 90-130V AC (60Hz)
180-260V AC (50Hz)
Power consumption: 85W
Environmental: Operation: 0-40 degrees C
Storage : -30 to 60 degrees C
Dimension: 360W x 335H x 375D mm

If you see anything out of the ordinary, let me know. From looking at my notes from other posts, the scanning freq. ranges are right. Chris Karchnak on Fidonet and a couple people here have seen Panasync's and like them. The Panasync's have 0.28mm dot pitch and the Wuztek has 0.31. Does it make a difference? Which one would be preferable?

The way I see it is, the Omnimon would cost $599 or I could go for a Panasync (approx. $450 plus Omniswitch ($80); roughly $550). The Omnimon comes with a switcher and a TSR for running mono and color at the same time via Revolver. Revolver doesn't work on the STe, so that does me no good.

Anyway, this compares well against a mono/color combo. Someone I know is willing to buy my color for $250. A mono monitor would cost, at best, $150 and then Monitor Master for $30. So, to round it off, it comes to around $450. The multisyncs have a 14" screen, which is considerably larger than the mono and even the color monitors. I use my ST a lot, so it may be worth the extra $100-$150. It's just a matter of figuring out which monitor to use.

There is also a Sony monitor, which I'm told is pretty good, so I'm looking into that one as well.

Before I decide, I think I'm going to wait for the reviews in the mags and try to get a look at that Sony.

Thanks for all your help!!

487. How much stack space do system calls need

Newsgroup: comp.sys.atari.st.tech
Date: 1990-10-31 09:26:45 UTC
From: teexand@ioe.lon.ac.uk
Message-ID: <1990Oct31.092645.28872@ioe.lon.ac.uk>
Source record: 50039

Is there a defined figure somewhere that specifies how much stack space is needed for TOS/GEM calls? When writing TSRs and Desk Accessories I don't want to waste more space than is really necessary. Obviously I need enough to stack the call arguments plus the SR and return address, but how much more is then required for the call itself - Rwabs() for instance, seems to need quite a lot of space. Any ideas?

It buffers both. Well, to be more correct: CACHEnnn itself buffers nothing
at all. It just extends the internal GEMDOS sector buffer list. So if
you find any erratic behavior concerning caching, blame it on GEMDOS.

Perhaps this has something do to with spikes on the RESET line
on the DMA bus. Since RESET is connected to nearly everything inside
your ST, those spikes can severely influence the behavior of your
computer. Especially the shifter custom chip doesn't like spikes.

This might or might not be the explanation of 'weird mode' (still
wonder how many colors you could get in this hyper-interlace
kind of mode 8-); due to the somewhat unstable design of the DMA
bus, there are probably other possible reasons.

Source record: 50025

hyc@math.lsa.umich.edu (Howard Chu) writes:

>Hm. With sufficient memory and a good cache, isn't the whole idea of a
>RAMdisk pointless?

Not in all cases (and that's true, even on machines with virtual memory). To take the example of compilation: most compilers produce a significant number of temporary files at various stages, which persist for only a few seconds before they are deleted. [GNU cc is an exception here - this is one of the reasons it's a memory hog]. At the same time, to the best of my knowledge, all the software caches for the ST are 'write-through'. This means that all files are actually written out to disk as they are made. [Again, if there are 'intelligent' caches out there, given TOS's insecurity, *I* wouldn't risk my data by using them in a development environment]. So, during a typical compilation, even though a cache will generally give an improvement in runtimes over no cache, use of a RAM-disk for temporary files will (except in some *very* particular cases) be even faster.

The choice as to whether to use a cache and/or a RAM-disk is very dependent on the particular work being performed. Especially on a single user machine like the ST, the appropriate choice will probably be different for the same user on different occasions [I certainly adjust these choices on my ST system - often several times within a session]. This is an example of system tuning. As an illustration of how bizarre it can get, I have an old PDP-11 which is largely used for program development. Of 4Mb memory, 3Mb is used as a RAM-disk, 740k as disk cache, and only 256kb as system memory space - odd, but that's the way it functions best *for that application*.

I don't have the pinouts handy, but before attempting this venture, you should be aware that the atari st requires an analog monitor (color and/or mono), of which the AT&T 313 (314) is definitely not suited for

Several months ago I removed 16 of the 256k RAM chips from my 1040, wired
in a SIMM dual SIMM socket, and inserted 2 1Meg (80ns) SIMMs. I now have
2.5Megs of memory that works great!

I don't know what you did wrong, but it should work.

493. The movep instruction & a strange display

Newsgroup: comp.sys.atari.st.tech
Date: 1990-10-31 15:56:03 UTC
From: mlake@irscscm.UUCP
Message-ID: <1990Oct31.155603.4066@irscscm.UUCP>
Source record: 50029

Greetings everyone.

I am having a problem with a 68000 program where the screen goes kaflooey at a certain point. I'm not fooling with the screen in my code, only the MFP and the sound chip. The program works ok except for the fact that it screws the display. I've traced the cause of the problem down to a movep instruction that occurs during a timer A interrupt. The movep is a weird instruction where it moves every other segment (depending upon the mode) of the source to the destination. Is it possible that my assemblers (the only ones I have are MADMAC and the MWC assembler, the latter being a real trip of an assembler) do not handle the movep instruction correctly? The same thing happens with both of the assemblers. I've seen the same code in other programs that work properly.

I'm open to any and all explanations and/or suggestions. Thanks.

Well, I use one on my four meg STE for all of the obnoxious temporary files that Mark Wiliams C insists on writing all the time. The GEMDOS caching scheme is a write-through cache (which I appreciate whenever I crash my system testing a program or someone turns my machine off!), but that means that You still at least have to write the temporary files out to disk before they get cached.

In an ideal worls, the compiler would see tht it had enough memory and use it. No, I take that back. In an ideal world, we'd have virtual memory so the compiler could _always_ use RAM... The OS would decide when it should go to disk!

As far as I know, there is no defined upper limit for the stack space needed.
Note that there may be other TSRs installed and linked into several vectors.
When you call Rwabs() for some hard disk partition, for example, the hard
disk driver is invoked which might use lots of stack space.

Howard Chu asks:

> Hm. With sufficient memory and a good cache, isn't the whole idea of a
> RAMdisk pointless?

Not entirely. I use Mark Williams C, which, as a three pass compiler writes lots of temporary files, not to mention the object files and the link file. I use a RAM disk to minimize the fragmentation on my hard drive, caused by all this file creation/deletion. The cache is to speed up access of the various programs, include files and libraries that the compilation needs.

Hello world
I have started using GEMINI and am finding it VERY good BUT (and this is
a big BUT)

My version of the Sozobon compiler (1.0?) bombs whenever I run any part of
it..

I replaced hcc, jas, and top with version 1.2 that i downloaded from some BB
a year or so ago and all the Sozobon bins still bomb.

Any applications produced with my version of the copilier bomb...

I have had a couple of hints about the problem (memcpy or something)..

BUT 'TOHRU NISIMURA's' new and improved version 1.2x of top doesn't bomb
under GEMINI - so, here is a guy who knows where his towell is!
Congratulations TOHRU

SO, is there somewhere in netland, a set of sozobon bins that all work with
GEMINI, or a set of sources and instructions....

Here's hoping
..Clive

People seem a little unsure of how GEMDOS's cache (the one CACHEXXX.PRG adds to) works.

There are two lists of buffers. CACHE030.PRG, for example, will add 30 buffers to each list. You can give it arguments to explicitly give a certain number to each list.

Both lists are write-through: all writes happen right away.

The first list caches FAT and root directory sectors. Any FAT or root directory access will use this cache.

The second list caches data sectors, defined as those which aren't FAT or root directory. Subdirectory sectors always use this cache. Normal file data sectors only use this cache if your program doesn't do reads and writes of complete sectors. Then the data sector is read into the cache, and the piece your program wanted is copied.

Whole-sector or multi-sector reads and writes don't use the GEMDOS cache at all. They always go straight to disk. That's where the other caches in the world can help.

With enough cache buffers, all of the FATs and root directories on all of the drives on your system will end up in the first cache and never be replaced. It's a waste of space to have more sectors in the first list than you have FAT and root directory sectors.

Having a lot of buffers in the data-cache list will mean that all your subdirectory sectors will get cached, and in addition the parts of files that get accessed as fragments, not as whole sectors. One example of this kind of access is in GEMDOS itself: Pexec reads the header of a file to find out how big it is, and since the Pexec routine only wants $1c bytes of data, the sector lands in the cache. Then, Pexec reads the text+data part of the file, and since it probably doesn't end on a sector boundary that last sector winds up in the cache. Finally, Pexec reads the fixup information, and that probably doesn't begin or end on sector boundaries, resulting in two more fragments. (The end of the text+data and the beginning of the fixups will be the same place unless there are symbols in the file.)

You can tell if you have "enough" sectors in each list by doing a "show info" from the Desktop on all your drives, then doing it again. If the second time doesn't actually hit any disks, it means all the FAT, root directory, and subdirectory sectors are in the cache.

Both caches are managed LRU: each time there is a "cache hit" on a buffer, it gets moved to the beginning of the list, and when the time

comes to replace a buffer, the replacement is chosen from the end of the list.

All this information is subject to change: I make no guarantees about the workings of GEMDOS's cache system past, present, or future.

Laser C has a file-level cache which is write-through for your source
code and delayed write-back for temporary files, object files, and
executables. It's amazingly easy to use, and much better than a RAM
disk as it's dynamic and you don't have to set anything up to use it.
On a 1 meg ST with floppies it must be a godsend -- even with a HD,
it's quite nice.

I know that incorrect code is generated for movep by both the 2.0 and
3.0 MWC assemblers. (Different incorrect code, too!) However, I'm pretty
sure that MADMAC handles movep correctly. (I've used it a number of times
with MADMAC and never had any trouble.) You can verify the correctness
of the MADMAC object code just by looking at it in the Atari debugger.
If it doesn't disassemble to what you're expecting, mebbe you're behind
a rev or two on MADMAC?

Sorry I can't answer your question. I look forward to you releasing the
code as I am very interested. Can I offer this observation. The ICD
board uses SCSI ID6 for the clock chip and & believe 7 is used by
Atari's laser printer. If you possibly use another ID or can you make
the code configurable at install time.

506. Sozobon C and Mupfel

Newsgroup: comp.sys.atari.st.tech
Date: 1990-11-01 11:42:24 UTC
From: jvt@its.bt.co.uk
Message-ID: <0M9%LP#@uzi-9mm.fulcrum.bt.co.uk>
Source record: 49943
Cross-posted to: comp.sys.atari.st.tech,comp.sys.atari.st

I hope someone out there can point me in the right direction to solve
this one.

I have been running Sozobon C under Gulam quite successfully for
some time now. Just recently I loaded Gemini (UK version) and
tried my applications under mupfel. They bombed (3)!

Wondering if it was my code, I wrote a trivial program "Hello World".
It also bombed no matter how I declared main().

Feeling rather devilish, I ran the compiler under Mupfel and it too
bombed. At least there's hope that it may not be just me.

However, the author of cmd.prg (sorry I've forgotten the name) announces
his code is compiled by Sozobon. It runs OK!

This last point makes me think its me & not the compiler of Mupfel.
Has anybody had this experience & know how to stop it? Kit is 1040STE.

Answers by e-mail preferred as my newsfeed has been disrupted of late.
I will summarize any replys this way.

John.

```

Several people sent me private mail and altogether I was directed to using wind_update() with the parameters BEG_MCTRL and END_MCTRL.

I am familiar with the parameters BEG_UPDATE and END_UPDATE but had not tried the other pair due to the lack of information on the differences in their function.

As you might already know AES is multi-tasking - it handles the GEM window and menu in conjunction with the functions built into ones program. BEG_MCTRL (and END_) disables the AES more than BEG_UPDATE; it prevents any dropdown, slider bar or window button from being controlled by the AES. If you use BEG_MCTRL then there is no need to also call wind_update with the parameters BEG_UPDATE (END_); the former is a superset of BEG_UPDATE functionality.

Case closed. FYI. Thanks.

512. MS-DOS Disk Compatibility?

Date: 1990-11-01 19:06:35 UTC
From: whinery@hale.ifa.hawaii.edu
Message-ID: <10122@uhccux.uhcc.Hawaii.Edu>
Source record: 49955

Greetings, ST-ites;

I am a non-ST person with a question. I have heard that ST disks
are compatible with MSDOS disks, and I thought I would make sure of that
before trying to send some GIF pics to my friend in New York who owns an
ST. Can I write GIF files to 720K 3.5" floppies and have him read them
with no problems? WHat considerations should I make? I might also ftp a
viewer for him, (he has not Internet connection) do executable need
special attention?

Alan
whinery@hale.ifa.hawaii.edu

I have a friend that has a Wuztek setup. He has problems with some programs causing a system crash. What seems to happen is the program in question attempts to change the scan rate on the monitor, and the monitor switches into mono mode (causing a system reboot). One such program is Altered Beasts. You may want to talk to the Wuztek folks about this before buying.

514. MiNT vs TDI Modula-2

Newsgroup: comp.sys.atari.st.tech
Date: 1990-11-02 00:40:07 UTC
From: ersys!arktik@nro.cs.athabascau.ca
Message-ID: <k2gZR1w163w@ersys.uucp>
Source record: 49949

I am really impressed with the MiNT kernel, however, I am still waiting for some brilliant Modula-2 programmer to create some modules to access the calls from this system. The reason it presents a problem is that the version of TDI Modula-2 I am using (Release 2.00a, I got it second hand, so I don't know anything about the upgrade policy, can anyone fill me in on this?) will not let me do GEMDOS calls via their number, they must be the ones prepackaged in the GEMDOS library.

I know it could be done with the CODE and SETREG statements, but I really do not want, or feel a need, to fire up Devpac, assembly up some code, dissasembly, and fool around for several hours, just to do something that TDI should already have packaged in with the system.

It would sure be nice to have a MiNT library for Modula-2, has anybody done this yet? Will anybody do this? Or am I on my own? In my opinion the language (which is Multitasking in nature in the first place) and MiNT are a perfect combination.

Thanks ahead of time,

```

515. Sozobon C fixes for JAS and dlib1.2

Newsgroup: comp.sys.atari.st.tech
Date: 1990-11-02 03:02:40 UTC
From: nisimura@srava.sra.co.jp
Message-ID: <4735@srava.sra.co.jp>
Source record: 49950

In article <284@aldetec.oz.au>, Clive Salvidge writes;

> I have started using GEMINI and am finding it VERY good BUT (and this is
> a big BUT)
> ....
> ....
> SO, is there somewhere in netland, a set of sozobon bins that all work with
> GEMINI, or a set of sources and instructions....

I have never played with GEMINI yet, thus I'm not sure this helps you.

Here is fixes to
o Sozobon Assembler, jas 1.1 .
o some routines in dlib1.2 .

Sozobon assembler sometimes produces incorrect codes for bit instructions;
bchg, bclr, bset, btst.

For example, in the case of "btst #4, d0", Sozobon asm would produce

```
+----------------------------+
| BTST d0 |
+----------------------------+
| 0 |
+----------------------------+
| 0 | bit number=4 |
+----------------------------+
```

instead of

```
+----------------------------+
| BTST d0 |
+----------------------------+
| 0 | bit number=4 |
+----------------------------+
```

The bit number word that shifted would be interpreted as a corrupted
branch inst. (WAO !!)

The bug exists in "opcodes.h"
the definition of btst is not correct.

```
{"btst$s", O_IMM, O_DN, S_L, "x0o40%1e", F_L },
^^^
F_B
```

the last field says "its immediate value should be coded in LONG."

Originally bit-instruction does have no size field.
Its operation size is implied by its second operand; data register

or memory data.

I changed "opcodes.h" table so as bit instructions must not have
size specifiers and their default sizes are F_B.

Also, some dlib1.2 routines have bugs. Worst one is in bzero.s.
bzero would make bombs in many cases. Fixes to them are simple.

Try to apply following patches, and recompile your jas and dlib1.2.

Thanks for the info! Does he have an ST/Mega or STe? Does he have the SoftSwitch installed? This may be the problem. From what I understand, you put their SoftSwith TSR before Revolver in the AUTO folder, so when you switch to a partition in mono, it switches automatically. On the other hand, this could hardly be the problem because he wouldn't be able to load Altered Beasts as a Revolver partition -- or could he? In any case, Revolver doesn't work on the STe, so I really wouldn't have a use for SoftSwitch. But thanks for telling me anyway. I'll ask Wuztek about it.

How's the monitor though?? How does it look? Is the color and monochrome good? How does it compare to other multisyncs or the Atari color and mono monitors? Thanks!!

517. Re: Reading both buttons from Eventmulti

Newsgroup: comp.sys.atari.st.tech
Date: 1990-11-02 07:48:51 UTC
From: csbrod@medusa.informatik.uni-erlangen.de
Message-ID: <3209@medusa.informatik.uni-erlangen.de>
Source record: 49957

dcrevier@jarthur.Claremont.EDU (Dan Crevier) writes:

>I remember a while ago people were discussing how to get an event from the
>right button _or_ the left button. I wasn't paying attention then, but now
>I have found I want to do that, and I can only seem to read events from both
>buttons pressed together. I think I remember the solution being simple.
>Could someone post the solution?

One method - undocumented though, but valid for all TOS/GEM versions -
is to add 256 to the number of clicks waited for. This negates the condition
for a return from evnt_multi due to clicks. Example:

```
mstate = 0
mclicks = 256+2
mbuttons = 3
```

This means: Wait for 'NOT both buttons released' = 'One button clicked'.

I know this is undocumented stuff but _very_ useful. And I would love it
if Mr Pratt or someone else at ATARI could promise us that this feature
will stay. PLEASE Mr Pratt - do us a favour. The only other way I know
of something like selective mouse click waiting can be done is linking
into the mouse vectors and - whenever the right button is clicked -
pretending that it is indeed the left one. But this causes much trouble
everywhere, and it is not even completely legal - after all, you have
to use those VDI mouse movement vector exchange routines that are
reserved for AES use only.

STs can read any 720 KB DOS disk around. The other way it is somewhat
more complicated: Most PCs don't adhere fully to the Microsoft conventions
for identifying disk formats, and early TOS versions produced _slightly_
incompatible disk formats (fixed since TOS 1.4, so this is an old story).
So your friend will be able to read GIF pictures as long as he's got
some GIF viewer program for his ST. If you can ftp him one, do so and
copy it onto the disk. No problems.

Programming some auto-folder programs, I have two short questions:

1. I want to trap some gemdos functions. How can I hang my routine in the system, and where do I find the parameters on the stack?

2. I want to overrule some GEM vectors from my auto-folder program. This has to be done after the desktop has been installed. What is the easiest way to detect the installation of GEM?

Please respond by email.

Thanks in advance,
Jan

520. Re Three bombs and Sozobon using Gemini

Newsgroup: comp.sys.atari.st.tech
Date: 1990-11-02 09:17:13 UTC
From: lrh@ukc.ac.uk
Message-ID: <6001@harrier.ukc.ac.uk>
Source record: 49960

I also found a bug in Dlibs1.2 in the initargs.c moudule.

It attempts to get the pointer to the parents basepage from the basepage, it then trys copy the environment from the parent if this is zero then it bombs as it is trying to copy memory location zero and to do this you need to be in supervisor mode. The fix is simply to add a line into initargs to check if the pointer is zero and do nothing if it is zero.

The reason that gemini bombs is because it passes zero for the pointer, I found that the debugger i use does this, and it caused programs compiled with sozobon to bomb.

A bug in hcc is after a function call has been made the stack is then tidied up

however this is the code it generates.

```
move.l #10,-(sp)
jsr _function
add.w #4,sp
```

the add.w #4,sp
should be add.l #4,sp

if it is a word sized add then eventually one day when by coinidence the stack crosses a 64k boundary then when it does the add then the stack will become trashed and the computer will crash.

The fix for this is simple - grep for add.w in src\hcc and find the appropriate one and then change it to add.l

then recompile dlibs, then recompile all binaries.

Luke.

Hi there.

I have had a Triangle Turbo 3 hard disk (48 MB) for about a year,
and I have decided that my disk 'layout' is hopeless - the sad part
is that I haven't a clue how to set it up. I mostly use gulam and
Sozobon C , and occasionally a word processor.

Would anyone be kind enough to suggest a sensible set-up, ANY suggestions
welcome.

Thanks,

David.

(My email is frazzled, so I'm using a friends ..)

>
> [I'm asking for a friend without usenet access]
>
>Graham
>======

The early 1985-vintage 520's came with TOS on a floppy. The machines had 6 ROM sockets. Two were filled with a boot ROM and the other four were empty. If this is your friend's situation, he should just unplug the two boot ROM chips and put in the 6-chip TOS 1.4 set. If he really has a later machine with a 2-chip TOS ROM set, then his best bet is to exchange the 6-chip TOS 1.4 for a 2-chip TOS 1.4 set. Both are available from Atari. I replaced a 2-chip TOS 1.2 set with a 6-chip TOS 1.4 set on my Mega-4 when TOS 1.4 first came out, and it was an awful job that involved removing chips on the motherboard, moving jumpers, repairing tiny traces that we accidently damaged, and so forth. I wouldn't do it again unless absolutely necessary.

>I'm back on the hunt for multisyncs...
>The way I see it is, the Omnimon would cost $599 or I could go for a
>Panasync (approx. $450 plus Omniswitch ($80); roughly $550)...

The Panasync is available in Santa Clara at Access for $399, $429 several other places. I'm inclined to think a Panasonic with .28 dot pitch would be preferable due to better specs, a better reputation, and lower cost.

>There is also a Sony monitor, which I'm told is pretty good, so I'm
>looking into that one as well.

I've made my ST work with a Sony 1304 monitor - good picture in color, .26mm dot pitch, but the cost is higher ($629 I think is the cheapest I've seen).

I went looking for hard disk PS's last year, and the ones that were suitable
were in the $90 - $150 range. I'd say $70 sounds pretty good.

the MWC assembler gets the reg reversed (my memory) on some movep instructions.

When I disassemble a program using certain movep , when reassembled, the
code is wrong. I believe the registers are reversed on movep r1,r2.

528. SCSI ID#

Newsgroup: comp.sys.atari.st.tech
Date: 1990-11-02 20:26:40 UTC
From: paulm@ccicpg.UUCP
Message-ID: <1293@ccicpg.UUCP>
Source record: 49964

Well after some further study I've come up with the following:
I reversed engineered the adpter board and it works very similar to the way
I've heard the adapter in an SH204 works. There is an adpter address decoder
that is hooked to data bits 5-7 of the ACSI bus. The output of this goes
to the PAL which qualifies this with ACSI CS * A1 and some SCSI signals.
An output from the PAL sets -SEL and SCSI D0 together (they are physically
wired together). On the first write to the host adapter #$88, #$ffff8606
does the host adapter and SCSI selection at the same time. Come to think
of it, I'm not 100% sure this is a BMS100. I got the board from a friend
who's drive box (it might of been an SH204) bit the dust. He just upgraded
to a different and larger drive and gave me the adpater.

Anyway, I think I have two choices:

A. I can alter the design to allow different SCSI selections by adding a
1-of-8 decoder chip ala 74LS138 to ACSI bits 0-2 and send the output
tri-stated by a buffer to the SCSI bus lines. This should maintain
compatibility with the disc driver since for selection a zero is on these
three lines anyways. Just setting them to 6 should set SCSI bit 6 and
due to the 1-of-8 get the radial selection bits.

-- or --

B. I can leave the Tape drive at ID 0 and just use another host adapter set
at a different ACSI address.

Currently I am tending to lean towards B (OK, I'm lazey :^)).

Anyways, what say you guys? A or B. As I said earlier, I'll release the
code to any and all.

The tape drive I am playing with is a Cypher 540 with the Emulex SCSI
'enhancement'. The code has the driver built in and is a klone of the
unix flavor of tar. It will tar in and out complete directory structures
or devices (ie. tar -cv c:) as well as files.

From: hans@wldrdg.UUCP
Message-ID: <420@wldrdg.UUCP>
Source record: 49968

```
Someone recently claimed that the code generated by hcc for the stack
is wrong. I.E.
add.w #4,a6
should be
add.l #4,a6
because you might cross a 64k boundary.

This is NOT a bug. There is no 64k boundary.
I quote from the M68000 programmer's reference manual (ADDA page):

Op-Mode field -- Specifies the size of the operation:
011 -- word operation. The source operand is sign-extended to
a long operand and the operation is performed on the
address register using all 32 bits.

Using 'add.l' instead will only make the instruction 2 bytes longer for no
reason.

csbrod@medusa.informatik.uni-erlangen.de (Claus Brod ) writes:
:dcrevier@jarthur.Claremont.EDU (Dan Crevier) writes:
:
:>I remember a while ago people were discussing how to get an event from the
:>right button _or_ the left button.
:
:One method - undocumented though, but valid for all TOS/GEM versions -
:is to add 256 to the number of clicks waited for. This negates the condition
:for a return from evnt_multi due to clicks. Example:
:
: mstate = 0
: mclicks = 256+2
: mbuttons = 3
:
:This means: Wait for 'NOT both buttons released' = 'One button clicked'.
:
:I know this is undocumented stuff but _very_ useful. And I would love it
:if Mr Pratt or someone else at ATARI could promise us that this feature
:will stay. PLEASE Mr Pratt - do us a favour. The only other way I know
:of something like selective mouse click waiting can be done is linking
:into the mouse vectors and - whenever the right button is clicked -
:pretending that it is indeed the left one. But this causes much trouble
:everywhere, and it is not even completely legal - after all, you have
:to use those VDI mouse movement vector exchange routines that are
:reserved for AES use only.

So what's wrong with alternating the value of mbuttons in the
loop containing event_multi()? On each pass through the loop,
check for only one button, and at the end of the loop change the
value of mbuttons to the other mouse button (ex-or mbuttons with
3). Easy.

This is completely legal, maintains consistency and context, and
it even works. I've used it myself. I can't think of any reason
that this idea might interfere with any other legal use of AES
stuff.

531. Using gdb (problems!!!)

Newsgroup: comp.sys.atari.st.tech
Date: 1990-11-03 18:50:09 UTC
From: david@doe.utoronto.ca
Message-ID: <1990Nov3.185009.7044@doe.utoronto.ca>
Source record: 49972

I have tried using gdb under TOS 1.2 and TOS 1.4, under RTX, Mupfel
and standard TOS, in MT-CShell and Gulam. In every configuration,
it bombs with the command "symbol-file". Here is what I tried:

```
gcc -gg -c hello.c
gcc_ld -o hello.ttp f:\gnu\lib\crt0.o hello.o -lgnu
sym_ld -o hello.sym f:\gnu\lib\crt0.o hello.o -lgnu
[run gdb]
(gdb) exec-file hello.ttp
[no problem]
(gdb) symbol-file hello.sym
[BOMBS!! (2)]
```

When I try it with -g instead of -gg, I get a bogon alert from
gcc_ld (it does not write enough symbols) and the executable is
buggy, but the "symbol-file" command does not crash (the program
will not run, though).

What am I doing wrong? The gdb binary is from atari.archive. Thanks.

Hi There.

I got a brandnew BioNet 100 Ethernet Interface, but the software
delivered with it is poorely working. X-Sessions bombing off, file
transfer sessions also.

Is there any public domain software on USENET working on this
interface, especially X-Windows or the like?
Is there PD software for the Atari ethernet interface card (X11
Windows preferred)?

Any help is greatly appreciated. Please respond via mail in regard to
network traffic. If there's interest in the answers, mail me, too.
I'll distribute them.

Thanks all.

Heinrich.

> Atari color and mono monitors? Thanks!!

> Ed Krimen .....

Just a quick note, I saw the Codehead's 16Mhz TT030 at the Boston Atari fest the weekend before last, and it was running with a Panasonic 1381 (the cheaper one that goes to 1024x768 interlaced .28mm dot pitch). There was some bowing of the screen on the far right, but ST Mono looked *great* on it, (as did TT medium rez, 640 x 480 x16 colors). I will be checking out the specs further (does the TT go to 70hz vertical refresh when running duochrome, or does it fake it?), and hopefully see another one running on some "PC" to double check the image quality. Current mail order is as low as $350.00 for the monitor (sans shipping and credit card surcharge?) and you know the prices and capabilities of the adaptor boxes and cables. Hey, I don't really! Could somebody post how those various adaptor cable, box and software combos stack up?? Thanks,

Bob Pegram

The problem is, you got to have an event_timer in your loop otherwise you
will never be able to change the values.
If there is no timed event, why should you specify it, and the gem-dispatcher
is doing more, than he must do.

Since this 'feature' exists since tos 1.0, it needs a simple "we will keep it"
from Atari to avoid 'workarounds' like yours.
If, on the other side, atari sais "this is subject of change" we have to use
this, or any other solution.
But I doubt, there is any solution, that is as elegant as
the above.

Greetings Dirk

537. Display blues

Newsgroup: comp.sys.atari.st.tech
Date: 1990-11-05 20:18:45 UTC
From: bill@mwca.UUCP
Message-ID: <1737@mwca.UUCP>
Source record: 49977

My mono display has been exhibiting weirdness lately - any ideas would be welcome:

The display starts flickering where vertical lines will be drawn approximately every eight characters, heavier at the top of the screen, lighter towards the bottom. It seems to be worst when I first turn on the monitor, although today it hasn't gone away. Fainter vertical lines are drawn between the heavier ones, and at times all the white areas of the display will become black, but there is a fuzzy white shadow near where the text would be.

My assumption is that this is a monitor problem, not an ST problem, for two reasons. First, using the ST with a color monitor works fine. Second, bouncing around the ST has no effect. Also, since the lines are fainter towards the bottom this seems like an analog problem, not a video memory problem.

Do these symptoms sound familiar to anyone? Any suggestions what to replace in the monitor, or should I take it in, or just scrap it?

Hello Wolfgang!

CACHEXXX.PRG gets the size of the logical sectors of the HD partitions
from the driver. It will adjust the size of the reserved buffers, so that
it will be the same as the biggest logical sector of your GEM or BGM
partition. I use a 48 MB BGM partition with AHDI 3.01 and CACHEXXX.PRG
and there are no problems.

Greetings, Olaf

++ puzzled - (what magic utility merges them?)
++ ..Clive

I feel it's worth posting a public answer, as it's a non-Gem area really.

Diff files represent the difference between two (text, usually) files.

This a common way of distributing optional patches to sources.

If a diff file represents a set of patches (sometimes across a number of files) the patches can be automagically applied using Larry Wall's "patch" program --- patch < source.dif. Both diff and patch are available on atari.archive.umich.edu

The tos/minix ports of GNU C are embodied in a diff file. Which leads me on ...

Graham (puzzled?, wait till you *use* it!)

543. Mouse vectors etc.

I'm trying to connect a serial PC mouse to the Atari ST. I've figured out how to read data from the serial port, and how to translate and inject packets into the mouse vector.

My question is: at what time in the OS startup is the mouse vector changed? I've got a driver that works when started from the desktop, but not when started from the AUTO folder. Which is weird, as I only call the routine pointed to by the mouse packet field of the result of Kbdvbase().

I must be one of the few ST users with a 3-button mouse :-).

Please let me know what you find when you see it running on a PC and about duochrome going to 70hz. A couple of people in c.s.a.s and someone on Fidonet have mentioned this monitor, so I've been looking into it. I picked up Computer Shopper last night and am going to call a couple of places to ask about specific specs of the C1381, like vertical and horizontal frequency ranges and frequency bandwidth, although I'm sure they'll be okay. (It's amazing how much one learns when he wants something good at a good price that works right.) I hope the "bowing" isn't too bad, but that's good to hear that the monochrome looked great.

- Current mail order is as low as $350.00 for the monitor (sans
- shipping and credit card surcharge?) and you know the prices and

- Could somebody post how those various adaptor cable, box and
- software combos stack up??

If I don't get on of the guys on Fidonet to make a cable for me, I'll probably go for Omniswitch from Talon ($75 mail order), but I really don't need the drive switcher and a couple of the other things it has. E. Arthur Brown has a switcher for $60, but I don't know how good it is. I may just spend the extra $15 for a quality product.

Speaking about stacking up, my monitor is going to be pretty high off my desk with all the things under it. I may need a stool! At the moment, I have an ICD case under my monitor, an under-the-monitor power-pad, and then two two-inch high blocks so the cables from my STe can go underneath everything. With the Omniswitch and the 14" monitor, it's going to be like sitting in the front row of a movie theatre! Just hope the show's good! :^)

>a rev or two on MADMAC?

The two versions of MadMac that I have both generate correct code for MOVEP.
But all versions of Megamax C and Laser C generate incorrect code for MOVEP.
(That's if youre using the inline assembler). The inline assembler also
generates incorrect code for DC.B and DC.L and some branch instructions.

Message-ID: <GJH.90Nov6202815@ghiggins.hpl.hp.com>
Source record: 49987

I received a canonical answer to my broadcast message to jbammi on
comp.sys.atari.st This has turned into a technical issue ...

Jwahar Bammi has left his postgrad position at CWRU and got a job as
a unix guru somewhere. Unless someone else is in a position to do so
and is willing, it means that there ain't gonna be any more updates
to the GNU C suite. (Version 1.37.1 is the last we have).

I have access to a Sun3 running OS4 here and have the GNU C distribution
sources plus JB's diff files for adding the ST-specifics. Unfortunately,
I'm neither C nor Unix literate, so am floundering unless all goes without
a hitch. It used to, but we've had an OS upgrade on the Sun and all bets are
off :-(

Can I invite all you GNU C users out there to join forces to try and keep
the ST versions of the GNU suite alive?

For example, the ST version of gas is 1.34, 1.37 is available and so are
the coff patches for gas 1.37. Does anyone know whether it's worth trying

1. The port of gas 1.37?

2. Applying the coff patches?

Is coff likely to be applicable to the ST architecture?

Is it worth at least getting an email list together?

Mebbe this explains the phrase in my 68000 book: "the MOVEP instruction
is probably never generated by a compiler..." The compiler writers don't
care about it and then their code can't generate it. Yeehah.

I've ask this question before (before I know about ~.st.tech) and no one said anything and I still haven't gotten around to trying it yet to see if my idea works.

Possibel idea on:

How to get a top non-scroll zone

In browsing SALAD last night I noticed a -ve variable V_CUR_OF (-30) that is the "byte offset from screen base to top of first cell".

Could not this variable offset into the screen where the first (scrolling) screen line would be; ie. a new (0,0) orgin. Then top area from 0 to offset could be used as a status area.

QUESTION: What is this variable actually meant to do??

What you are looking for is Larry Wall's patch program. This utility
takes an old file and a diff against the new version as input and
recreates the new version as output.
The source and a st binary can be found for example on cs.uni-sb.de
[134.96.7.254].

554. RAM Upgrade Horror story

Newsgroup: comp.sys.atari.st.tech
Date: 1990-11-08 09:49:19 UTC
From: kentd@FtCollins.NCR.com
Message-ID: <KENTD.90Nov8094919@zappa.FtCollins.NCR.com>
Source record: 49893

Hi All,

Since a lot of netters seem interested in RAM upgrades, I thought I'd share my RAM upgrade horror stories with you all (as well as a plea for advice/comments). If you're an accomplished ST technician/ hardware hacker please share some insight with me on this one.

Here's the deal- Machine: 520STfm, Board: Zubair Z-RAM

First, I get the board, plug 2Mb of 80nS DRAMs into it, and do the installation, pretty easy, so far. I boot the machine and notice that as it comes up when the disk drives are active the screen gets darker, but no big deal. I run both of the supplied RAM tests and it passes without a hitch. I'm the proud owner of a 2.5Mb machine. Wrong. After having the thing installed for a while my disk files start to mysteriously become corrupted. Everytime I write something to disk there's a 50% chance that the file I just wrote has been munged. Looking at an ASCII file reveals many of the characters have been incremented by one- i.e. a space turns into a !, a * turns into a +, etc. I check the board for shorts, opens, good connections, etc. Everything looks OK.

So, I call up Zubair with the above story, it sounds like he's seen this problem before. He asks what brand of RAM I'm using.

"OKI", I say.
"There's the problem", he says, "get some low drain DRAMs, like Samsung."

He cheerfully sells me 2Mb of 80nS Samsung chips. I put them in my machine expecting all my troubles to disappear. Nope. Now the thing won't even pass the memory tests. Using one of my OKI chips, I check all the Samsungs to make sure one of them isn't bad. Nope, that's not it.

I call Zubair again: "Try shortening the cable between the MMU and the board". I do this. The board now passes all tests. Great, the ordeal is over. Wrong again. After a couple of minutes of C programming my text files are being trashed again (in exactly the same way they were w/ the OKI chips!)

Yet another call to Zubair... this time they can't come up with any useful suggestions.

What I now have: 4Mb of DRAM, a pcboard, a 512K ST, A lot less money :^{

So, if anyone has suggestions on what can be done, what the problem may be, etc., I'd love to hear them. The only other symptom aside from the disk drive's inability to write are "lines" of pixels that are darker than the others running vertically up and down the mono screen. My current

theory is that my power supply is too weak... but I'm not going to try a new one until I can determine if this is truly the problem.

558. Scolling lists in GEM

Newsgroup: comp.sys.atari.st.tech
Date: 1990-11-08 17:26:49 UTC
From: adp@csug.cs.reading.ac.uk
Message-ID: <1990Nov8.172649.14731@csug.rdg.ac.uk>
Source record: 49897

Hi there folks.
Just a few questions on some bits and pieces that I need some help with..
(Please)

1. I am currently learning GEM, and want to know how one implements a
scrolling list, as in the file selector. I would be extremely grateful
for any help here.

2. I also asked recently for any help with hard disk set-ups - one chap
replied and said "Not enough info..", so here goes.

520 STFM (to be upgraded to 2.5 MB in a week)
48 MB Triangle Turbo 3 HD
Star LC 24-10 Printer
Mono monitor

I (mainly) use :
Gulam
Sozobon C (and want to use gcc after memory upgrade)
FirstWord (well, it does the job..)

I may use Gemini, Neodesk or my own shell using MiNT.(dunno yet)

All I want is some suggestions for useful (and sensible) partitioning
and directory structures. Ta.

3. When I write my shell using MiNT, I want to use XARGS, but I dont know
the standard implementation details - I guess I mean the standard format.
Can anyone help me here ?

Thanks in advance,
(I saw some guy write 'thaADVANCEnks' - isn't that the wrong way round ?)

I once knew how "low-level" St graphics worked but forgot :-(
That is, there are the 4 bit planes and a color table and good stuff
like that. Would someone care to explain it in detail? How it is
different for the Ste?

In a similar vein, how does horizontal/vertical sync palette swapping
work (to get more colors)? Trade offs? Any source examples to look at?
I have the graphics format file but some of it doesn't make sense, like
the Spectrum format...

My Ste is on the way, I'd love to be up to speed when it arrives! Thanx.

Cheers,

Joe

I've gotten a request or two about the STOS .MBK sprite file format and so I'd like to add a descrption of it to the picture formats list. I have the description from the back of the STOS manual but it seems to only describe the format of "sprite banks" in memory, not as they are saved to disk.

Anybody know more details on .MBK files? I must confess I don't know that much about STOS so perhaps I'm missing something...

>Kbdvbase().

Must be when the AES come up. The ROM jumps over exec_os, then does
some Dgetpath and Dsetpath calls to get its view on paths right,
and at some time opens a physical workstation which is when the
mouse vectors are probably being initialized. You will have to
implement some technique for checking whether your program starts
in the AUTO folder, make it resident and sit there and wait for the
AES to come up. I'm not sure that there is any decent and documented
method for doing things like this. Moving your routines to a DA
might solve your problems.

From : Steve Davies , Inmos , UK
Date : 9/11/90
Subj : IBM Monochrome on the Atari ST.

I'm sure that this question has been asked before but ....

Is is possible to use an IBM (well Viglen actually) monochrome
monitor on the Atari ST 520 STFM computer in high res mode ?
The monitor I have is specified to 60-70 Hz.

If it can be done then how ?.

Please could you Email any response (as well as post) because
our server is flakey.

Thanks for any help,

Steve.

566. Re Sozobon C & Mupfel (Summary)

Newsgroup: comp.sys.atari.st.tech
Date: 1990-11-09 13:16:58 UTC
From: jvt@its.bt.co.uk
Message-ID: <{=%^*=$@uzi-9mm.fulcrum.bt.co.uk>
Source record: 49905
Cross-posted to: comp.sys.atari.st.tech,comp.sys.atari.st

THE ORIGINAL QUESTION: How do you stop Sozobon C and programs compiled
by it crashing under Mupfel (Gemini's Shell).

Thanks to Ant <ant@mks.uucp> and Bob <balkwill@encs.dnd.ca>
for responding to my posting. Their advice was to fix the bit
manipulation code in the assembler and the memcpy()/memmove()/bzero()
fns in dlibs. Basically this worked, but not without problems.

The first thing I discovered was that I had 1.01 of Sozobon so I obtained
1.2 and remade *everything* = MAJOR MISTAKE. This caused every thing in
sight to behave strangely. My application, which runs under Unix, MS/DOS
and TOS1.6+Gulam fell apart at initialisation, Sz Make could not find
cc,jas etc when run under Mupfel (yes it did not bomb) but it was
OK with Gulam. After *much* tracing I found the problem in a fn call
where fn(&structure, int1, int2) produced *strange results*. It seemed
the params got scrambled with int2 taking int1's value, int1 became 0
and the pointer was left alone. Recoding as
fn((long)&structure, int1, int2) got it to behave but at this point I
decided things had become *extremely* *silly* and there must be some
other cause.

I decided the only way was a structured approach taking each change
at a time. The biggest problem was actually knowing which mods to
make. So many fingers being in the pie and an absence of any
controlled release of patches from the authors makes the whole thing
a nightmare. OK thats enough of the moans - here is what I did the
second time through, starting with the original 1.01 binaries & sources.
At each numbered stage the resulting code is installed.

ACTION EFFECT

1: Modified dlibs12 alloca.s bzero.s Application still bombs
memcpy.s as in Tohru Nishimura's
Mailing.

2: Corrected the hcc bug in fun.c from No Test
a reposting from Johann Ruegg (the
only note I have from an Author!!!)

3: Corrected jas opcodes.h - again No Test
Tohru's posting. Two worries here
a) I found another & completely
different version of opcodes.h
purporting to fix the same bug!!!!
Sorry I have no details, they're

on the m/c at home.
b) Tohru's explanation of the faulty
lines does not match his diff output.

4: recompiled dlibs functions of 1: plus Application now runs OK
lmemcpy.s which also had a bit instr.

5: Make *all* binaries including Application & Compiler runs OK
upgrades to hcc 1.2 and top 1.2
also mods to peep2.c peep3.c
reposted by Michal Jaegermann.

I have not installed the mods to initargs.c from lrh or top1.2x from Tohru.
This is because it now works and these unofficial patches, while maybe
being a good thing , will only stack up problems should 1.3 or
whatever be released.

OK thats it. I hope this tale will help others to avoid the pitfalls.

As a parting shot - A MESSAGE TO THE AUTHORS, how about releasing
patches on a regular basis through c.s.a. Then there would be no
confusion and an otherwise excellent package would not be spoilt
by poor followup.

John

Try changing that to:

31r meta.sys ; Meta File
^
this "r" seems to be important
>[...]

I wrote a program that wrote out metafiles, and I needed put the
magic letter there. But I notice that some programs (Pagestream 1.8) do
not need it there. How do they do it? My program crashes big time if I
leave it this way and try to write something out to a metafile.

569. Cross-Compiling on a SUN

Newsgroup: comp.sys.atari.st.tech
Date: 1990-11-09 16:24:56 UTC
From: jlong@radc.af.mil
Message-ID: <1990Nov9.162456.27441@lonex.radc.af.mil>
Source record: 49908
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

I find myself in the unique position of getting to play with my favorite toy at work!! We are using an Atari to drive a digital error injector unit that is able to inject random errors into any digital link up to T1 rates. We have been compiling using MWC, but to get really quick we would like to use GNU-C on either our SUN-3s or one of our SPARC-stations. I know the ports to cross-compile on a sun were maintained by Jwar Bammi (sp?) at dsrgsun.ces.cwru.edu, but that machine hasn't answered the internet in ages.

Does anyone know where else I can ftp the stuff I need to set up a complete cross-delevopment system on a SUN to compile some straight-forward TOS type programs for the ST (no GEM stuff). We hope to develop on the SUN, dump to

the atari using the RS-port and execute away. I would really appreciate it if someone could help me out on this, as I have long been the lone ATARI fanatic here at work and would like to capitalize on this golden opportunity to show the MS-DOS types here in the lab what our trusted machine can do!!

I would appreciate talking to someone who has done this type of cross-compiling ASAP!! Please leave me E_mail or post the replies if you can't get to me using either of these addresses:

A while ago, there was a thread on cross compiling from Sun OS to Atari TOS. A couple of problem issues where discussed but I don't remember anything conclusive.

Is it possible to cross compile from SunOS to AtariTOS?

Is this done with gcc?

Are patches available?

Thanks,
Eric

572. 16-bit (ST) meeting Wed Nov 14/90

Newsgroup: comp.sys.atari.st.tech
Date: 1990-11-09 19:47:14 UTC
From: daroloson@watmath.waterloo.edu
Message-ID: <1990Nov9.194714.9219@watmath.waterloo.edu>
Source record: 49911
Cross-posted to: uw.sys.atari,comp.sys.atari.st,comp.sys.atari.st.tech

Kitchener-Waterloo Eight Sixteen Thirty-two (KWEST) Atari user group
16-bit (ST) - Wednesday, Nov 14, 1990
DCS Course Room, Room 2009 (2nd floor)
Math & Computer Building, University of Waterloo
Room opens at 7:00 pm. Meeting starts at 7:30 pm.

The following is a list of new items that I personally will
be bringing to meeting. If they are not discussed in the formal
part of the meeting, they will be available for demonstration during
the casual segment.

* Megafile 44 removable hard drive

* NeoDesk 3
NeoDesk CLI (Command Line Interpreter)
NeoDesk Icon Disks

* Universal Item Selector III

* Mug Shot (police identification kit type program)

* Word Quest Powerpack (crossword and word search generators)

* Games Galore (4 STOS games)

* Telegram (Kid program)

These products and more will also be reviewed in this month's "The Hard Copy"
which should be our biggest issue ever.

Also in this month's issue:

* Report about Atari Canada at the last Brantford meeting.

* Report on the WAACE show in Washington (Hope to get video before meeting).

* Info on the Canadian Computer Show and Windsor/Detroit International
Atarifest

* Other news and reviews

Also, at this meeting members will receive a disk containing the catalog
of the newly re-organized library.

The ST meeting is also the deadline for article submissions in the Cordless
Mouse contest. The new item from Practical Solutions, the Video Key,
will also be at the meeting.

> the coff patches for gas 1.37. Does anyone know whether it's worth trying
> 1. The port of gas 1.37?

I have recently done the gas-"port" for version 1.37. It was almost trivial. The new version is available via anonymous ftp at cs.uni-sb.de in directory /pub/atari/gas (sources) and /pub/atari/bin/gcc/lib (binary). Whe i finished the port, i was rather surprised that it produced even better (= smaller) code than gas 1.36.

BTW.: We have here an almost complete collection of all GNU software ported to the Atari ST running TOS (there are plans to set up a Minix archive too, but it may take some time).

Source codes of SPICE2/3 are not hard to obtain. Besides from Berkeley directly, I believe long time ago someone uploaded it (SPICE2) to Genie. The problem is to port it under TOS. I wouldn't take this as a hobby at home (maybe some FORTRAN and ST guru will :-).

Foruntately, spice3 is in C. I don't imagine it should be _too_ bad on
a compiler with a nice floating point library... But what do _I_ know
about porting long scientific programs?

Hello Everyone:

I have a copy of the Sozobon C Compiler version 1.2 (I think) and would like to start writing GEM Applications. Looking through the book Atari ST Application Programming by Pollack and Weber it appears that I'm missing a couple of header files: GEMBIND.H, GEMDEFS.H, and OBDEFS.H. Does anyone know a FTP site that I can copy these from? I'd also be interested in any tips on getting started. Thanks for the help.

SPICE3 is the C version and has hooks for the IBM PC built in to it. So
maybe it wouldn't be too painful to port.

After 3 weeks sweating to get NetNews support in out lab, I finally get it working.....and 1 month later---our main mail-serving machine, the one I was getting my NNTP newsfeed from, goes public with NetNews for all its users to use!! Isn't that the way it always works with computers??

Anyway, the purpose of this posting is to see if anyone can steer me to an alternate source for the GNU-C ATARI<->Sun cross-compiler. As we all seem to have discovered, Jwahar Bammi seems to have been transported out of this galaxy by aliens looking to use his prolific programming skills for their own purposes (in other words, he hasn't been heard from on the net in a long time) and he maintained the complete set of programs I needed.

Could some kind soul please point me in another direction for this information?? FTP is the prefered means of getting the files!

Capt Jeff Long
longj@lonex.radc.af.mil or jlong@cassiopeia.radc.af.mil

PS: the purpose of this repost is to make sure the transition locally of the News program didn't keep my last plea for help from making it outside of our own local domain.

Holy willikers BATMAN there is an ethernet card for the Atari!

At first I though this guy was off his rocker, but its a message
from europe and, as you know, europe is were its at and the US market
positively sucks the silicone for anything new and exciting.

I would die for an ethernet card, or an X11 terminal program! Each one,
I hear is readily available everywhere, except in the US!

Thats probably simple to explain, the US can't build cars, and we can't
even build simple software!!!

OR

Atari is ONE STUPID turkey. Which do you guys think is the correct answer?

From: <>
Message-ID: <1990Nov11.013428.4566@cs.utk.edu>
Source record: 49923

I want to be able to write setup information directly to a program file.
(This has been done in several applications -- ARCSHELL 2.1 is one
example). I figure that I will have to mess with the Getmpb procedure,
as well as the structure of the executable files, to find out where a
variable "lives" on the disk file. Alas, the documentation for that
stuff is *very* unrevealing, and I don't want to resort to trial & error.

I would really appreciate any suggestions, example code (C please!),
or at least a pointer to a book (he he) which carries such information.

Please e-mail to andrew@cs.utk.edu.

Thank you so much.

585. Bad news for Panasync

Newsgroup: comp.sys.atari.st.tech
Date: 1990-11-11 02:39:40 UTC
From: ekrimen@ecst.csuchico.edu
Message-ID: <1990Nov11.023940.10838@ecst.csuchico.edu>
Source record: 49925

I did a little more research today on the Panasync, to perhaps reveal some bad news. First thanks to George W Dinolt (dinolt%wdl45@wdl1.wdl.fac.com) for providing me with specs of the ST's monitor output, and thanks for these people for providing it through the grapevine: Harri Valkama LAKE<hv@uwasa.fi>, Lea Viljanen <ladybug@clinet.fi>, and ldp.dec.com!weaver@decwrl.dec.com (Dave, DTN 297-7141, MRO2-4/E33).

Atari
low medium high
------- ------- -------
Horizontal Frequency: 15.8kHz 31.5kHz 35.7kHz
Vertical Frequency: 60Hz 60Hz 71.2kHz
Horizontal Resolution: 320 640 640
Vertical Resolution: 200 200 400

I called one place (Lyco) and asked for the vertical frequency of the monitor. They said it was 50 to 90, which should work with the ST. Then they said the horizontal was 30 to 37. This looked a little strange, so I called another place (Harmony Computers in NY) and asked the same questions. They replied the same. Which means, if I'm not mistaken, that there would be something wrong with the ST's low resolution, since it's lower than 30. If anyone can find something wrong with my assumptions or data, PLEASE let me know. I also asked about the frequency bandwidth, which Talon recommends should be 35Mhz or better, and neither of the places knew what it was on the Panasync.

Talon also recommends that the vertical auto-sync be 15 - 36Khz or better and the horizontal auto-sync be 45 - 90Khz or better.

This puts a real damper on things. At least I know this BEFORE buying the monitor.

(Howard Chu, what was the horizonal frequency on your monitor again?)

The above data for the medium resolution is wrong.
Both low and medium resolution have the same Horizontal and Vertical
Frequencies (those listed above for low resolution).

Both low and medium resolution are compatable with standard color TV sets.
(on European STs these rates change e.g. Vertical is 50Hz, not sure of Horz.)

Could someone mail or post an concise explanation of the assign.sys file...
I am trying to get Opus to work, but for some reason it won't find my fonts
in the folder listed in my PATH=.

Could the problem be the fonts? A description of a standard GDOS font would
also be helpful, as I have no idea if I have standard fonts (They are from
atari.archive, DVIFONTS and other collections of fonts, I think)

Is there a collection of genuine GDOS fonts anywhere?

As you can tell, I'm just starting to fool around with fonts and GDOS, and
have found no sources of information on how all of it works.

Thanks

I am after information, good or bad on the MEGADRIVE host adapter. This is used in Gasteiner Hard Drives. Anyone with any experience could they please inform me.

Muchos thanks in advance.

592. Getting Unix windows to run....

Newsgroup: comp.sys.atari.st.tech
Date: 1990-11-12 04:30:47 UTC
From: rcte2p@jetson.uh.edu
Message-ID: <7588.273dd117@jetson.uh.edu>
Source record: 49931

Has anyone actually managed to get Unix windows running (uw)? I ftped uw from the atari.archive at umich.edu and everytime I try to ru the program (uw.prg) it loads for a while and then it just hangs and I have to reboot. I am using the provided startgem.prg to have uw.prg automatically run if that is important, but I tried to run uw.prg by itself and it still hung...

593. Ram expansion questions....

Newsgroup: comp.sys.atari.st.tech
Date: 1990-11-12 04:58:40 UTC
From: rcte2p@jetson.uh.edu
Message-ID: <7589.273dd7a1@jetson.uh.edu>
Source record: 49932

I have a question about Ram expansion. I have a 520ST that was expanded to a total of 1Meg with the Easie ST solderless Ram board by AERCO. I am now thinking of expanding my ram to 2+ megs. My first question:

The ram board (bank1 or ST memory) has 2 banks of chip sockets, with currently 1 set filled to making up 512K which, I was wondering if I went and added more ram to that extra bank would the board still function properly (thus giving me a wierd config of 1.5megs total)? BTW, are these 64K-bit or are they 250k-bit chips?

I did inquire sometime ago about adding 1mega-bit chips to the board and I was told that CMOS 511-000 @120ns or better were fine. First, what exactly are 1M-bit chips and how many are required to make 1Meg ram? 8? What are the current prices for 1M-bit ram chips and where could I get some? Anyone else have this particular Ram board and any info on it?

Your problem makes me think of the one I currently have with my computer. Some time ago, it also started to corrupt my files, and I finally noticed that the bit 6 of odd (or was it even) adresses was systematically turned to 1. Perhaps you have the same problem with bit 0. My probelm is not related with a memory upgrade: it happened by itself. Unfortunately, I still not have my computer back, so I can't say you what the trouble is.

It was simply called CAP and was posted in comp.sys.atari.st in 1987,
but I think some files were truncated and no repost arrived at our site
since then. It was posted by maccarle@ed.ecn.purdue.edu. I think the
address of the author was Peter_VerBruggen.HENR801c@Xerox.com. But I
don't know whether those addresses are still valid.

>HOW does it work?! I can't figure it out. ARgg...

Double-click on pft.ttp, and type in: <Original filename>[Space]<New packed filename>. You can unpack with LHarc just as if it were a .lzh file.

Also, if the packed file is larger than the original file, it will not be written.

This is one of the best packers I've seen. Much faster than Pack-Ice.

Source record: 49937

I have an olde version of the Atari ST dusting away in a remote corner.
It has got 1 meg of RAM (upgraded old 520 ST). Since I would like to
continue using the machine for a while, I was wondering about a few
things:

1. Upgrading the Atari TOS (my ST has got it in ROM).
I would like to have a disk based version of the OS, so that
I can upgrade easily, both now, and in the future.
Possible???

2. MAC emulation. Which is the best? What about MAC ROM's?

3. Hard disk. Which (for MAC-emulator, ST, and MINIX
compatibility)

That was all I guess. Thanx in advance for any response.

598. Looking for Rest-Proof RAM disk for Mega 4 ST

Newsgroup: comp.sys.atari.st.tech
Date: 1990-11-12 16:08:03 UTC
From: ralph@laas.fr
Message-ID: <RALPH.90Nov12170803@orion.laas.fr>
Source record: 49938

When I had a 1040 ST I used to use etrnl2.prg and was quite satisfied with it. I now have a Mega 4 ST and it has become unusable! (I do remember the net discussions concerning the proper test for 4 Mb.)

I have recovered etrnl3/4.s - a version of resizable reset-proof ram-drive modified to work also on Mega4 - that was posted to comp.sources.atari.st (Volume 2, Issue 85) by Michal Jaegermann. I have *not* been able to assemble this on my machine. I have both Sozobon jas and GNU gas. Not being an assembly language person I am not interpreting very well the tons of diagnostic messages that these assemblers provide. Do I need another assembler? Or do I just need to know how to massage the source code? I have tried to contact Michal Jaegermann (mj@myrias.COM) but have been unsuccessful.

Since I've been a successful user of etrnl2, I would appreciate to get etrnl3 to work. Otherwise, I'd love to hear about RAM disks that work on Mega 4 Sts. For the moment I am using the non reset-proof SI_RAM desk accessory.

Thanks,

and other horrible symptoms...

>My assumption is that this is a monitor problem, not an ST problem...

After receiving mail from several people (thanks!) suggesting both monitor
and ST problems, my further experimentation has indicated a _monitor_
problem - I've made a cable for use with a Sony 1302 multisync in mono mode
and there is no indication of trouble.

One suggestion was that the circuitry in the monitor which differentiates
between low and high (light and dark) may be getting flaky - this sounds
reasonable based on what I see. It is interesting that vertical lines were
seen on exact character boundaries, though perhaps there is a slight variation
in signal level at these points which is enough to affect the monitor. At any
rate, I'll be taking it in for repair in a few days.

As a side note, the Sony works reasonably well as a mono monitor, though
characters aren't quite as clear as on the SM124 (which makes sense
considering there are three beams for each pixel, as opposed to one on the
mono monitor). I could wire up only R, G, or B, but none of those three
color choices sounds too appealing. There is also some slight bowing of the
screen near the top...

>I want to be able to write setup information directly to a program file.
>[...] I figure that I will have to mess with the Getmpb procedure,

Oh, boy! Getmpb has NOTHING to do with locations of things on disk. No wonder you got confused! Getmpb is a BIOS call which is used by GEMDOS to find out the lay of the land at the beginning of the world: it is the BIOS's way of telling GEMDOS what memory it found and where. It should not be used by user programs. (Gulam used this for the "mem" command and that's one reason the "mem" command doesn't work in Rainbow TOS.)

In the Hitchhiker's Guide to the BIOS there is a discussion of the format of an executable file on disk. It starts with a header, then the image of the text segment, then the data segment, then the symbol table, then the "fixups" which tell GEMDOS how to relocate your program. (Programs are linked as if they start at zero, and the actual starting address of the program is added to all absolute references by Pexec(). The fixup information tells Pexec what places need fixing up.)

My modem went dead a few weeks ago so I sent it to be fixed. When I got it back it worked fine (on another machine). My ST no longer sends out a terminal ready signal. I tested the port with a mini rs232 tester (the TR LED did not light). Any advice on what to check once I open the hood? I have opened my ST many times before but I never paid much attention to the modem port. What IC's can I expect to find hanging on the port. Any advice would be greatly appreciated. Thanks in advance.

-
- Atari
- low medium high
- ------- ------- -------
- Horizontal Frequency: 15.8kHz 31.5kHz 35.7kHz
- Vertical Frequency: 60Hz 60Hz 71.2kHz
- Horizontal Resolution: 320 640 640
- Vertical Resolution: 200 200 400
-
-
- I called one place (Lyco) and asked for the vertical frequency of the
- monitor. They said it was 50 to 90, which should work with the ST.
- Then they said the horizontal was 30 to 37. This looked a little
- strange, so I called another place (Harmony Computers in NY) and
- asked the same questions. They replied the same. Which means, if I'm
- not mistaken, that there would be something wrong with the ST's low
- resolution, since it's lower than 30. If anyone can find something
- wrong with my assumptions or data, PLEASE let me know. I also asked
- about the frequency bandwidth, which Talon recommends should be 35Mhz
- or better, and neither of the places knew what it was on the Panasync.
-
- Talon also recommends that the vertical auto-sync be 15 - 36Khz or
- better and the horizontal auto-sync be 45 - 90Khz or better.
-
- This puts a real damper on things. At least I know this BEFORE buying
- the monitor.
-
- (Howard Chu, what was the horizonal frequency on your monitor again?)

Ed,
I used the Thompson's UltraScan monitor on my Mega4ST. I paid $375 for this multisync monitor approximately 3 years ago. It's a great monitor! Multisync, multipurpose! It works with all 3 graphic modes on my ST. Lots of connectors in the back. I plug my MegaST (Low/Med/Hi), My VCR, TV turner, Genesis system, and my IBM 386 compatible running VGA, all in the the same monitor!!! The bad news is that Thompson (french company) is no longer sell this monitor. I heard that the Mishubishi's DiamondScan monitor is the same as the Thompson's. I saw the DiamondScan in the local computer swapmeet, and it costs $350 brand new! You might want to give it a try.
Good luck,
-Steve SteveLa@csulb.edu

604. Home built hard drive info wanted

I'm considering putting together my own hard drive set up and have several questions:

1. Is there any magazine article or other reference that describes what the Atari ST requires?

2. What type of drives does it require, if anything special? Reliablity of a given manufacturers drive info also.

3. What adapter boards are available? I know of one put out by Berkley. Reliability of the board info here too.

4. Any warnings on what not to do. Or tricks learned in doing it yourself.

5. Good sources for drives, adapter boards, cables, power supplies, or cases.

I'm not concerned about building cables or anything like that, as I've had a bit of experience there (provided I've got a reasonable schematic).

Please email at my address below and I'll post the results if there's some-thing worthwile. Thanks to all who help.

^^^^
Surely this should be 15.8kHz, the same as for low res, after all they both work on a standard TV set, which has 15.8KHz / 60Hz rates. (50Hz in UK)

> Vertical Frequency: 60Hz 60Hz 71.2kHz
^^^
a typo - should be in Hz
>
>
> Then they said the horizontal was 30 to 37.
^^^^^^^^
Seems a restricted range for a true multi-sync, this range in more appropriate for VGA only. Does this monitor work with CGA? (CGA uses the same frequencies as low/medium res). The shop may be more knowledgable about the monitors performance with PC graphics standards.

>
> Talon also recommends that the vertical auto-sync be 15 - 36Khz or
> better and the horizontal auto-sync be 45 - 90Khz or better.
>

Are the above back to front...
i.e horizontal (line) sync range 15kHz to 36kHz
vertical (frame) sync range 45 Hz to 90 Hz

This is comparable to most multi-sync monitor specs, and should work in all 3 Atari modes. Note the 45Hz spec allows the monitor to be used in the UK (and Europe) with our 50Hz frame rate.

Seems like a very good price monitor, can you give details of the supplier or manufacturer - I would be interested in locating a UK source.

<stuff deleted>

It depends on what you mean by running. I ftp'd uw.tar, uw.arc,
and uwbin.arc(I believe those are the file names). I built the
server on my workstation(contents of the tar file) and used the
wind.prg on my atari, and I am very pleased with the results.

First I ran wind.prg on the atari, phoned into work(you can define
the function keys to do this for you), and ran the workstation
version of uw.prg. This allowed me multiple windows to my workstation.
I was unable to get the reverse(a window to the atari from my
workstation) using uw.prg, and the equivalent to wind.prg on the workstation.

I apologize if I have the names of the programs, or files wrong,
but they should be close enough to figure out the actual files
I mean :-)

(Thanks for answering whilst working on your thesis)

That was my thought. The thing actually works up to the point the desktop
finishes writing the folder windows, and then the mouse freezes. I have
not yet disabled the normal mouse, and that continues to work.
I guess I have to do some debugging, tracing the contents of vectors etc..
(Yes, I have killed the Rsconf() call so the control panel does not reset
the serial port.)

611. Re: Location of variables in executable files.

Newsgroup: comp.sys.atari.st.tech
Date: 1990-11-13 14:47:21 UTC
From: andrew@cs.utk.edu
Message-ID: <1990Nov13.144721.21402@cs.utk.edu>
Source record: 49851

I was thinking (erroneously) that Getmpb would tell me where the program
being executed starts in memory, so that I can match the location of
the variable in the "self modifying" program and on the disk. Now that
I've learned more about the format of the executable files, I know better.
The suggestion I received was to look at the initialized data segment,
and look for my magic number. This sounds like it might work, but seems
like a bit of a hack.
I suppose there is no better way of doing it, so I'll try it the hack-way.

Thanks to all who responded to my query, I appreciate it very much.

I'm typing on it now - works like a charm (in monochrome, I don't think it
works in color). Great program, I only wish it supported VT100 instead of
ADM31, though with rebindable function keys you can play some tricks (such
as making the ALT-FKEYS send VT100 keypad codes).

615. Using an AppleColor RGB monitor with a ST

Newsgroup: comp.sys.atari.st.tech
Date: 1990-11-13 20:00:47 UTC
From: rlcollins@miavx1.acs.muohio.edu
Message-ID: <2870.27400aa0@miavx1.acs.muohio.edu>
Source record: 49855

I would like to take my ST to work with me, but I hate lugging my monitor around. At work we have two Apple IIgs's with a RGB monitor. Here are the specs on it:

Scanning Frequencies: NTSC/60
horizontal 15.734 kHz
vertical 60 Hz

This seems to be in the right specs, the only problem is the cable. Here are the pinouts:

Pin Function
1 Red Video ground
2 Red composite video
3 composite sync
4 not used
5 green composite video
6 green video ground
7 not used
8 not used
9 blue composite video
10 not used
11 not used
12 not used
13 blue video ground
14 not used
15 not used
Shell Shield ground

I have no idea how to come up with a cable so I can use it.

I too would be interested because I am in the exact situation that Paul is in.
Is Aerco still around? I suppose I should try to call them to find out. Now
where is the folder with the boards documentation...

Ha I found it...!
The infoI have says that you must install 16 TC511000P(120 ns or faster)
drams to get a total of 2.5 meg. I guess I ought to buy the ram and try it.
However, I seem to remember someone saying this board isn't exactly plug
and go. Anyone no anything about this. Thanks...

Anyone have source code for playing sound samples on old STs? I can easily play 'em on STEs, but I'd like to write a program that runs (albeit not as well) on old STs too.

Thanks,

Steve

P.S. I imagine it's a trick with using all three channels to set to neither tone nor noise and varying the volume to generate sound, but I'd like to see code because I don't know how to use the timers, either.

622. Running Unix Windows - Summary

Newsgroup: comp.sys.atari.st.tech
Date: 1990-11-14 13:46:30 UTC
From: rcte2p@jetson.uh.edu
Message-ID: <7617.2740f656@jetson.uh.edu>
Source record: 49862

I want to thank everyone who helped me get Unix Windows (uw) to work. Here is a summary of what I was told:

First, IGNORE the read.me file and don't use the startgem.prg to autoboot uw. Uw.prg is NOT the program that you want to run -- it will lock up if you try to run it directly. Win.prg is. So, click on win.prg and then you should soon be in the program with a blank terminal screen. Configure the program to how you want it to be (i.e., RS232, Function keys, Default path....) and then save the configuration.
Next, make sure that you have uw on the host end and properly compiled for the system you are on. I am running mine on Ultrix 4.0 (4.3BSD) so it compiled just fine.
Now connect to your host, logon and then run uw on the host side (remeber, you are already using the atari side of uw as a terminal). Now just open windows as you need. Each window is a separate process. There are also utilities to help you run certain protocols, and tools to help make your windows nicer.

Now for some comments:

1) Not to slow, even at 1200 baud, but I would like to see so more buffering of a line before it is drawn on the screen....

2) My biggest quirk is that I can't redefine the backspace and delete keys. When I use Uniterm, I have the two keys reversed but in uw, the backspace sends a ^H which means nothing to my host. I might look into the source abit on that one, but for now, I will just use X-utilities to redefine my keyboard.

I must congradulate the authors on this great program. I even got a response to my problem from one of them. Thanks to everyone.

>>A couple people ask question about the AERCO memory board.

I recently upgraded mine from .5M to 2M.

I used Hitachi 1Mx1's (HM511000AP12) @ 120ns for $6 apiece from
Microprocessors Unlimited Corp. Without any documentation, I accidently
installed the chips in the sockets where the 256Kx1's were (well, they
fit! :-). Actually, they go in the other bank of sockets; the near bank
as you look at the board from the front of your ST. The sockets in that
bank have exactly the right number of holes. The easiest way to do the
installation is: remove the PCB from it's connectors, destall the old
RAM, install the new RAM, and reinstall the board on it's connectors.

There is no need to change anything about your ST or RAM board to do this
upgrade (except the RAM :-).

Have fun with 2.5M! I do.

PS If you want the phone number of Microprocessors Unlimited I have it. The
prices may have gone down since I bought my RAM.

The first place I would start is Dave Small's article, "Megabytes, Not
Megabucks" in STart, vol. 2, no. 3 (Winter 1987). You don't need to worry
about device drivers, although you will need some partitioning software.

Basically, you will need:
1) a drive
2) a disk controller
3) an Atari-controller interface (and the folks who sell these often
supply partitioning sw as well)
4) a case & power supply
5) cables
6) time & patience

If you don't have access to back issues of STart, email me and I'll try
to summarize the info in a way that doesn't violate anyone's copyright.

Hope this helps!
Max J.

Check the 1488 chip (input on pin 2 from YM2149 and output on pin 3 to pin 20 (DTR) on the RS232 connector. You don't say what model ST, but it's the same pins on 520, 1040 and Mega; so you should be able to get it fixed.

|> I want to be able to write setup information directly to a program
|> file.

I once posted a fundamental (as I think) article against self-modifying code to this newsgroup. Here it is again - slightly generalized and of course open to consideration and discussion:

---------- cut here ----------

No, no, no! Never write self-modifying code!

Self-modifying code is very bad style. It is difficult to write and even more difficult to understand. Programs that modify itself tend to be unmaintainable.

A lot of machines do not allow you to modify a program file for security aspects. Consider everyone on a multiuser system would be allowed to modify any file. Sure, this is not true for the Atari ST, but one should learn to do it the right way. Spend some time to figure out how to do it on e. g. a Unix system and you can to it equivalently on the ST. (Slight simplification here, but you got the idea, right?)

On a related topic: Several systems do not even allow you to modify your executing program while it is located in memory. You will only be allowed to write to the data portion of the program. This is due to the fact that on a multitasking system several tasks can execute one single program simultaneously. Now, if the program code can not be modified by the executing task it is sufficient to load the program into core only once, thus gaining a lot of efficiency. (Of course each program get it's individual data section.)

If you are afraid of virusses don't modify your program file. You (the average user) can never tell whether the program has been modified by a virus or not. There are programs on the market (including the PD market) that estimate a certain checksum for each program and alarm you if this number changes. How could such a program tell if the change is due to a virus or not?

If you are afraid of virusses write protect your media as far as possible. A program that writes to its program file needs to be run from a not write protected disk. This a unnessary and an avoidable security hole.

In most cases it is fully sufficient to maintain a configuration file. Keep an entry for every variable that needs to be modified permanently. Upon startup of the program the whole stuff is read in again and the

program's variables are set accordingly. Simple, isn't it?

Re: your question posted to comp.sys.atari.st.tech for info on how to modify variables in an executable file, there are a number of ways.

I assume you need to modify the variables in a disk file--i.e. you are not looking to change them in a running program, to un-fixup the program, and then to write them back to disk. That could get real hary. I can think of two easy ways to accomplish this. One requires some assembly. The other requires you to leave symbols in the executable. I'll describe the former. The latter is the method used by GNU C top do just what you are looking for.

Finding the executable on disk

The first step is to find the executable on disk. This may be easy or difficult depending on the TOS level and on the type of program you are running. TOS does not store the name of the currently executing process in an accessible place, but the AES does store this if you Pexec from an AES program and use the following in your init routine, before adjusting paths and such:

```
char myname[128], command[128];
appl_init();
shel_read(myname,command);
```

Unfortunately before Rainbow TOS, the rscrc_load() function and others trash the shel_read() buffers. TOS 1.4 onward doesn't exhibit this problem. On return from shel_read() myname will contain the name (and possibly the path) of the executing process. Command will contain the command from the invocation of myname.

A simpler way to find the name is to require that it remain constant and to require the program be invoked from its own directory. Then you don't have to find it--it's always where you expect.

Modifying variables

The TOS executable format requires each program (even overlays) to begin with a 28-byte header. This header "disappears" once the program is loaded for execution. More accurately, parts of it are stored in the executable's basepage. The so-called magic number (0x60 0x1a) that must be at the start of every executable file is actually a bra.b 0x1a instruction, which on earlier Alcyon 68K systems caused execution to begin at 28 bytes passed the beginning. TOS does not interpret the magic the same way, but execution begins with the first address of the .text which is 28 bytes past beginning of the header. The effect is the same.

You can store variables right after the beginning of the .text as long as you jump around those variables. With a little figuring, you can safely modify those variables on disk and save the results. Here are some code fragments:

```
* This fragment sets up the variable table
* Must be first object file in link statement
*
.globl __start * this is the runtime entry routine in gemstart.s
.globl _vartab
.globl _var1
.globl _var2
.globl _var3
jmp __start
_vartab:
_var1: dc.l 0
_var2: dc.l 0
_var3: dc.l 0
```

```
/* this C fragment opens the file, finds the current variable values, and
* changes them
*/
char buf[3*sizeof(long)];
char myname[128], command[128];

appl_init();
shel_read(myname,command);
if ((fd=Fopen(myname,2)) < 0) {
Cconws("Cannot open ");
Cconws(myname);
Cconws("\r\n");
Pterm(fd);
} else
Fseek(0x22L,fd,0); /* now points to vartab */
Fread(fd,(long)(3*sizeof(long)),buf);
modify_buf(buf); /* make your changes */
Fseek(0x22L,fd,0); /* 0x1c + sizeof(jmp __start) == 0x22L */
Fwrite(fd,(long)(3*sizeof(long)),buf); /* write them back */
Fclose(fd);
```

I've used the above in a number of programs without problems. Hope yo find this useful.

[...good reasons deleted...]

And perhaps more immediately relevant to ST programmers: you will regret writing self-modifying code when/if the TT is generally available. S-M code doesn't play well with instruction caches, which the 68020, '030 and '040 all have. Even building code on the fly, e.g. in a stack buffer, can cause havoc if you have both data- and instruction-caches and the D-cache isn't a write-through cache. S-M code is a "neat hack" that probably everyone is intrigued by at some point, but: "Just say no!"

Have you ever pressed <ALT>-D in Uniterm? It drops DTR to the modem.
However, pressing it again *doesn't* reset it. What's the magic key
that resets DTR again?

Ron

Ok everyone, repeat after me:

All hail the Mac resource forks
All hail the Mac resource forks
All hail the Mac resource forks

Maybe this is the next thing Atari can standardize :-) Now that the
PC+Windows has it (like outline fonts, graphics independence, etc.)

I guess that's the bummer part of having an Atari (or Amiga): even cool
system-safe addons have to be done in-house.

637. 5.25" disk problems

Newsgroup: comp.sys.atari.st.tech
Date: 1990-11-16 19:12:56 UTC
From: fishs@s1001.essex.uk.ac
Message-ID: <4400@servax0.essex.ac.uk>
Source record: 49877

Hello,
I am new to the NET world, so excuse any breaches in Netiquette.
I use an Atari 1040ST/E (TOS 1.06) at home, with an external 3.5" D/S
disk drive, and a 5.25" external 40/80 track switchable disk drive.

Anyway, I download a fair amount of stuff from Panarthea onto our
University SUN 3/50's. Then I can only put them onto a 360K 5.25" disk
on an IBM (I haven't access to any university 3.5~ drives).

I find that my new STE won't read IBM 5.25" disks. I have to format an
IBM 3.5" disk, run PC-ditto, copy onto it, then I can use the software.

My 520STFM could read IBM 5.25" 40 track disks from the desktop, does any-
one know why my STE can't.

Any help greatly appreciated. Please either post if it appears to be a
common problem or mail me (if you can) at : fishs@uk.ac.essex

Thanks in advance.

```
OK, I will sumarize. The right way to find a cursor position
is, to initialize the linea trap with:
linea0();
then to read:
V_CUR_CY
and/or
V_CUR_CX
This works by me, and under MWC.
I tried to thank all the responding netters separetely, but a
lot of my reply mail bouced. Hope that at least this one goes
thru the net :-)

Thanks at all.
Roger.
```

Everybody hold your horses. I seemed to have (unintentionally) started
another virus discussion (but I was suckered into it, you see).
I like to torture my ST with interesting projects (and isn't this a
perfect machine for such a purpose ?). In particular, I was trying
to think of a way to write a demo program which, by a simple bit
toggle in the executable (once some kind of password is entered),
becomes a fully-functional program. Of course an external data
file would do as well, but I know how to do that already...
Anyway, I have absolutely no interest in viruses, except possibly
how to get rid of one once I have it. There.

Since I'm posting this, I might as well ask a few more questions.

1) What's the deal with the mouse display ? It seems that when I call
graf_mous (or whatever the name of the AES routine is) to turn
the mouse on several times, the levels get nested, and the mouse
display becomes very queer (i.e. leaves a trace, or sometimes
disappears, etc.). Is there a way (short of installing my own
mouse handler) to tell on which 'display level' the mouse is, and
to set it straight ?

2) In dialog boxes: if there are several editable fields, is there
a way to specify in which field the cursor should be ?
Is this a random process, or does the cursor default to the top
field ?

Thanks for your answers in advance.

-andrew krzywdzinski (andrew@cs.utk.edu)

Try the line A variables CUR_X and CUR_Y. Offsets -28 and -26 (decimal) from
the line A base pointer. In assembler, you could do...

dc.w $A000
move.w -28(a0),cur_x
move.w -26(a0),cur_y

- Darek
```

>interface and drive, why would anyone choose anything else for his or her ST?
>
>-Roy Wood.

Why wouldn't anyone want to buy an interface and use a standard hard disk?
Is that your question?

Here's my answer...

A Supra hard drive interface costs $100, if you can still get one. There is
a better product out now (I should know, I bought the Supra) from ICD, and it's
about $130 mail order. This is called a HOST ADAPTER. Everything is an
interface these days, so let's keep things clear.

The Host Adapter plugs into the ST's DMA port (one of the very wise parts of
an ST) and converts these signals to be SCSI compatible. You can have up to
10 DMA devices, and data rates have the potential to be 2 Megs per second
through this port. Fast!

Okay, so that's a start. You mentioned cheap IBM-PC style drives. But now we
only have SCSI compatibility. Whoops! So you need to convert from SCSI to
ST-412/506 now, if you want to use an off-the-shelf MFM or RLL-encoded PC type
hard disk. What now?

Well, the best and easiest choice is to get an SCSI compatible drive instead.
This costs $30-$150 more than an equivalent ST-412/506 hard disk. The other
choice is to buy a second "adapter", which converts from SCSI to ST-412/506.
These come in both MFM and RLL flavors, and Adaptec is a good choice. They
sell them for about $130, depending on the model. It will let you connect
TWO cheap PC-type hard disks with one board. An extra savings...

But now you need a hard disk, and hopefully one that's supported by the Supra
or ICD formatting software. Otherwise you need a lot of specific information
about your disks. And you need a box. And you need a power supply. And you
need cabling. And you need the luck of the Irish, because if just one of all
those connections you made is flaky, it is a long, arduous trail. It takes
very sophisticated equipment to debug a hard disk setup -- or lots of trial and
error.

If you approach the chore correctly, you can do all this, save $50 - $200 over the cost of a mail-order ready made hard drive, and have a dependable machine. If, say, you get a bad part in the mail (which one) it is sheer hell. I went through all of this about two years ago, and wound up with a 65 Meg hard disk after six months of struggle. Not only did I get a bad hard disk, I got a bad Adaptek SCSI-RLL adapter!

I'd still do it again, rather than buy a new setup. It has run without fail since then, and I need more space now.

644. Atari megafile expansion

Newsgroup: comp.sys.atari.st.tech
Date: 1990-11-17 19:53:44 UTC
From: swklassen@rose.uwaterloo.ca
Message-ID: <1990Nov17.195344.22424@watdragon.waterloo.edu>
Source record: 49884

I have an Atari Megafile 60 which is filling up fast. It is possible to expand this without shelling out all the money for a second megafile 60? Specifically, can I simply add another drive to the interface in my current Megafile?

Here are the details:
- my drive has the number SEA{something} on the back. Someone told me once that this meant it was a Seagate drive.
- ratehd tells me that the adapter is an Adaptek {something}

I know that I could expand things by purchasing another megafile and chaining it onto the DMA, but is it possible to expand the one I've got now, say from 60 meg to 120 meg, by adding another drive mechanism to the current controller? Physically there seems to be lots of room in the megafile box.

No, prior to this I have never pressed <ALT>-D. Interesting.
>However, pressing it again *doesn't* reset it. What's the magic key
>that resets DTR again?
I trust Simon must have documented something about this in his manual,
however just playing arround I find that <ALT>-L (long break with DTR off)
can be used to restore DTR. There probably is another key that just restores
DTR by itself, but right now I don't know what it might be. <ALT>-L is
good enough though.

648. Gauntlet II four player option.

Newsgroup: comp.sys.atari.st.tech
Date: 1990-11-18 21:24:47 UTC
From: thaanuj@prism.CS.ORST.EDU
Message-ID: <21847@orstcs.CS.ORST.EDU>
Source record: 49888

My local atari dealer (45 miles away) just opened a new store and had a grand opening sale last week, where I picked up Gauntlet II by US Gold at a pretty good bargain. The docs mention a four-player adapter. They are sold mail order for about $12.

What I am wondering is what this thing is and how complicated it is. I have heard that is is just a plug that goes in the parallel port with two DB-9 jacks. If this is so, could somebody tell me the pinouts on the parallel port and how they are connected the the joystick jacks?

I'm really not so stingy as to avoid the $12 charge to buy one, but I am aching for a small project to do to help kill some time.

Thanks for any and all advice I receive. Happy to pass along to others whatever I find out. Just let me know.

>Can some cleverer person tell me why the GEMINI console window fonts work
>under AMCGDOS but are garbled when I try to use G+DOS??

I can't quite remember the specifics, but it's something to do with the fact that GDOS fonts can be in Motorola or Intel format (there's a flag in the font header somewhere to say which). AMCGDOS seems to support fonts in both formats, but both GDOS and G+PLUS only support Intel format fonts.

The Gemini font used in the console window is probably in Motorola format.

You may be able to fix this with some kind of utility, or assign the same font id that the console font uses to a different font.

651. MWC fread() = slow

Newsgroup: comp.sys.atari.st.tech
Date: 1990-11-19 16:17:08 UTC
From: paulm@ccicpg.UUCP
Message-ID: <4163@ccicpg.UUCP>
Source record: 49791

Hi, I am now putting the finishing touches on my TAR program for the ST and my SCSI cartirdge tape drive that writes and reads UNIX compatible tar files on tape. It works fine but one problem showed up when I added the -b (block buffering) option: the read from the disk is 4 to 6 times slower than the write to tape! I was using MWC's fread with stat and other releated calls to maintain UNIX type compatiblilty with the directory elements (ie. mtime, mode, and others). I know that my disc will read MUCH faster using the Fread gemdos call but I am unable to find the Handle element in the FILE *structure. I tried porting and recompiling under sozobon and although it reads the disc magnitudes of times faster, I am having problems passing the stat structure pointer around. Can anybody help me out on this?

BTW: tar also supports the -f {filename} flag to create tar files on disc instead of tape. I am also thinking of adding the Streaming Disc feature that the latest Backup thread has been talking about.

This will backup multiple partitions to tape, file or streaming disc until all is backed up, or space on the tape/disc runs out.

When completed, I will post binaries and sources of both the tape driver and tar program.

THANX in ADVANCE, Paul Moreau.

652. Executable Symbol Table

Newsgroup: comp.sys.atari.st.tech
Date: 1990-11-19 17:50:24 UTC
From: ericco@ssl.berkeley.edu
Message-ID: <ERICCO.90Nov19095024@soc1.ssl.berkeley.edu>
Source record: 49792

Is there a good reason for executable files to have symbol tables in them? I've been poking around various pieces of executable code, and I've found references in the symbol table (I think) to routines like printf, etc. I know on SunOS4.0 a special symbol called "__DYNAMIC" is used to indicate that shared libraries are needed. I don't think that there is anything like this in TOS.

Does this mean that one could load program into memory, and then call functions withun them as *subroutines*, if you knew the functions interface, and used compatiable compilers, etc?

Thanks,
Eric

swood@vela.acs.oakland.edu (EVENSONG) and bd6@vax1.mankato.msus.edu ask about the "TT developer's package." I don't know of such a thing. You can buy a TT and buy the Developer's Kit (which is to say, "Become a developer"), but I don't know of a "TT Developer's Package." And you don't need to "become a developer" in order to develop software on the TT. All you need is a TT and a compiler.

Becoming a developer for Atari means you get a pile of documentation, a compiler (Mark Williams C), and, most important, a phone number. That phone number is your line to Atari Developer Support, which can answer questions, help with your marketing, and generally support you as a developer for Atari machines.

Please write to Gail Johnson, Atari Corp. Developer Support, 1196 Borregas Avenue, Sunnyvale, CA 94089 for details, and application, or more information.

There is an article describing what to do on ub.cc.umich.edu in PC7:4jadapt.arc.
You can get it by anonymous ftp. (I know, it probably *is* on atari.archive
too, but I was too lazy to open a connection there to find what directory it's
in...)

>I'm really not so stingy as to avoid the $12 charge to buy one, but I am
>aching for a small project to do to help kill some time.

>Thanks for any and all advice I receive. Happy to pass along to others
>whatever I find out. Just let me know.

This will probably take you all of 10 minutes to put together. You just need
a 25 pin connector for the parallel port, 2 9 pin connectors for the joysticks,
and, um, 12 strands of wire. Hoods for the connectors are nice, too. I found
that a plain ol' 9-pin D subminiature connector works fine.

If that doesn't work for you, you can always cut up two Radio Shack joystick
extension cords and plug those into the 25 pin shell. That's guaranteed to work.
I like those extension cords, I use them just to get the jack to a reachable
location. Especially since I have 3 different joysticks that I use for different
styles of games, and want to change 'em quickly...

Sorry to stir up the pot with what seems to be a now-dead subject, but I don't recall the resolution of all the horror stories, and now have a (horrifying) 1040STe of my own to deal with. The main problem I'm having is that just about everything that loads up gets partially written onto video memory. I get vertical lines, I figure 16 pixels apart. I would have expected a plain-old overwrite problem to wipe out a couple rows, starting at the top of the screen. Instead I get 1 pixel wide vertical lines, evenly spaced out, and occasionally the bottom of the screen gets trashed. What's going on?

The STe arrived with the STE_FIX program in the AUTO folder of its language disk. Can't boot into medium resolution without it. Yeehah.

Along other lines... I just started using ICD's boot stuff with this new host adapter... Apparently, whenever the driver detects a write failure, the thing shifts the video into medium resolution. What I'm seeing is on my multisync monitor in monochrome mode, all of a sudden there'll be a glitch and my screen has been divided in half, vertically down the middle. Everything is drawn in both the left and right halves of the screen. The screen borders are resized, and look like the color rez borders, but everything stays in black and white. The preferences menu still says high rez. This is incredibly annoying, as well as making some stuff unreadable. (Although some of it is interesting, really. Anyone for a 4 pixel wide font? 160 columns of text. Oooo....) It says it's version 4.8.4, by the way.

659. RS232 file transfer between PC and ST using RTS/CTS

Newsgroup: comp.sys.atari.st.tech
Date: 1990-11-20 19:04:38 UTC
From: gary@brb.isnet.inmos.co.uk
Message-ID: <302.27497e46@brb.isnet.inmos.co.uk>
Source record: 49799

I am attempting to connect my PC clone upto my Atari ST using RS232. I want the link to run at 9600 baud and use hardware handshaking (RTS/CTS etc). Note: I do not want to use XON/XOFF.

I am led to believe that there may have been/still are bugs in TOS which prevent hardware handshaking from working correctly. Note: I have November '85 UK ROMS (TOS 0.98?).

I have been using a RS232 LED breakout box to try to figure out why the PC cannot send (copy fred.dat COM1:) data at this rate to the Atari (running a comms package) without dropping data (when the screen scrolls - suprise, suprise). If I connect CTS and DSR (on the PC side) to RTS (on the ST side), nothing gets copied across, as the ST sets RTS to -12V, and the PC will only send when the DSR and CTS are at +12V (wouldn't you know it!!). However if I connect DSR and CTS directly to +12V, then do the copy, the ST's RTS pin goes immediately to +12V, then after a short delay (until the receive buffer fills up?) starts "rattling" (trying to stop the sender sending?). This almost seems correct - it is difficult to tell.

Question is: is there a known patch. I am sure other netters must have cracked this problem before. I have traced the RS232 machine code using MONST2 and a copy of the ROM disassembly in Atari Internals as a reference (he says donning a flame retardent outfit :-) and it seems that there is no way to patch in new RS232 routines, short of a patch to the TRAP#13 handler.

Intriguingly Atari Internals shows a table of vectors for Bconin (etc) around address $512, but I think this is for a slighly later version ROM than my own.

Comments?

The monochrome mode is not as sharp as the Atari SM124 monitor.
You need to adjust the 'sharpness' on the monochrome mode. The
display is quite good in this mode. I saw a multisync monitor from
one of the booth (Wutek) in the Anaheim Atari Show that has a very
good display in the monochrome mode. The company, Wutek (spell??) is
located in southern California. Good luck.

Assembly language debugging is much easier with symbols because function names and variables appear by name rather than address. Most commercial executables won't have the symbol table as it just swells the executable size, though. Not all Atari languages will leave the symbol table in the executable, and not all debuggers understand it, either. Laser C and Devpac assembler both do the right thing, for what it's worth. If you're looking for an excellent assembly language debugger, I recommend MonST, which is packaged with Devpac. (The Laser debugger is also an excellent source debugger, and a passable assembly debugger as well).

>Does this mean that one could load program into memory, and then call

I can confirm the Gemini fonts are in Motorola format. I haven't tried it,
but I've just got Fontkit3+ from the ST Club which should be able to do
the conversion. It's a good thought as it may solve my problem of having
to switch GDOS's for Timeworks as the print fails under AMCGDOS.

Some notes on using O.E.M disk drives on Ataries
the Driving power of the YM-2149 that is used to
drive the drive select and side select is only
one LS load, this meens that all O.E.M. drive
fall out side the specs, they use 1 K Pull up
resistors, you will find that on Atari Drives
that these are removed or replaced with 2.7 K
resistors, Note: this is only on the Side select
and Drive select lines..
There was some info on this in a Elector Mag. some time back
I still have the Mag: but not handy at the moment, but it
was on about putting a Buffer in those lines 7417 i think
I have never seen any othere mentions of this that the
YM-2149 OPs are only 1 LS load..

I've seen the same thing (with the double mono screen - a cheap two-page monitor!) This happened when I was using a multisync in mono mode - overnight I turn off the monitor but leave the ST on - when I came in the next morning and turned on the monitor I saw what you describe. I suspect it has something to do with the synchronizing circuitry in the monitor becoming confused (in my case, when I turned on the monitor with the ST already on). Perhaps your ICD driver/STe is pulsing the horizontal sync in such a way that the monitor gets confused...

667. Save--Use--Restore MFP timers, help wanted.

Newsgroup: comp.sys.atari.st.tech
Date: 1990-11-22 08:46:24 UTC
From: fk@vall.dsv.su.se
Message-ID: <1050@vall.dsv.su.se>
Source record: 49807

Hello NetPeople and NetBeings.

I`d come across a question which I`d be happy if you would discuss with me. I`ve begun to suspect that there is no easy solution to the problem behind it.

IN SHORT: is there a canonical, clean and Officially Approved way of restoring the Timer Data Registers in the MFP MC68901 to either the values they where initialised with before my program touched them, or their initial, reset values?

I am working on a program (real-time audio pitch converter) in which I need two timers. The documentation I have describe the MFP`s timers like this:

Timer A: applications and end-users
Timer B: horizontal blank counter
Timer C: System clock 200 Hz
Timer D: RS232 baud rate

Timer A is of course available. I hope that timer D can be restored by reading and restoring the RS232 configuration via TOS.
Timer B is an enigma. Does it count pulses or does it generate them? If it generates them, would using timer B cause problems (like frying the monitor?). Timer C runs at 200 Hz and I guess this is equal for most ST`s and MEGA`s; it could be restored by simply set to run at that frequency.

I also speculate that reading the Timer Data Registers (TADR, TBDR, TCDR, TDDR) is pointless, since they contain not the initialization values but the current timer count. Reading and restoring the other registers (Interrupt Enable Reg., Interrupt Mask Reg, Vector Reg. and the three control registers) are probably alright. The application acquires the total execution context while using the timers (IPL 5, only timer interrupts allowed).

The simple way out is of course to do like a game: you can't exit unless the computer is reset. But I`d rather be able to use and restore the MFP at will, without horrible side-effects.

So, to sum up my questions:

- What is the usage and initial settings of timer B?

- Is there a clean way to obtain and restore the Timer Data Regs.?

I will be happy for every comment and reply, email preferred. Any scrap of trivia, pointers to documentation or previous postings

is welcome. A summary will follow the resolution of the problem.

BTW: the pitch converter works, the problem arises when it is time
to clean up and leave. Those of you who are interested can have
source and binary in jas assembler and Sozobon C. You`d also need
the Replay cartridge (the old one, with one input and one output)
from Microdeal. Routines for other samplers could very likely be
fitted as well. The program also does echoing, but that
needs only one timer.

Fredrik Kilander, fk@dsv.su.se.

Well don't try to pull them out, they don't come out that way
they have little clickers to hold them in (upright) unclick
the clickes, very frajile, then swing board down to 50 Dec,
or say 10/2 o'clock, then just lift out, no force needed
you can use 120ns or faster simms, also it is posible to
use 9 bit ones, al la PC. you have to use 2 simms to make
up a bank, if you have 512k now, you can put in 2 one meg
simms this will give you 2.5 megs, i have seen talk that
STE's will not work with 2.5 megs unless you have a Patch
program, this could be wrong as a freind has one and will
work with 2.5 megs, but i did not check which bank had
the 1 meg simms in, but there was a program that would not work
with 2.5 megs, we think that is did its own memory clear, and had a bug
that did not like 2.5 megs, also note. it is posible to have
a STE with Sipps in them...hope this helps

Just a simple question after I put out the system specs:
Atari Stacy4 running Mint06 off a D: partition.
How can I get MGR to open a window?
All I get is "Can't get a PTY" when I try this.
I didn't see anything in the docs on creating them.
Thanks in advance Harry

I looked at a friends megafile 30 recently, and if the 60 is the
same, the only thing that has to be done is ad the connector for the
small (34?) pin scsi cable. The Megafile board has both the acsi and
the scsi boards on one big board. They left the connector for the
second drive control cable off, but sucking out the solder and putting
one in is probably pretty easy.

OUCH!

Firstly apologies for including most of the original but I felt deletions
would destroy the sense of Howard's message.

I too have an ICD host adaptor with the same software. However I do not
have STE_FIX and I am certainly not getting most of these problems. The
only one I get is not booting Med-Res if the desktop is saved in Lo or Med.
One *simple* fix I've found is to save the desktop in Hi-res then when
you boot with a colour monitor it comes up in Med.

I believe there is a hardware bug in the latest ICD board. I have contacted
them & they are sending me a daughter board "which will cure it".
Cannot confirm yet as Snail Mail is still doing its worst!! The
problem is around noise on the DMA bus. To see if you have this problem,
turn on write verify. If it reports error, you probably have read errors
also. A short term fix is to find a DMA lead which allows the disk
to write without error but it will vary from drive to drive. This

may be the cause of your other problems - no promises though.

John.

673. Programrunning from ACC ?

Newsgroup: comp.sys.atari.st.tech
Date: 1990-11-23 16:18:21 UTC
From: hagelin@pommac.lne.kth.se
Message-ID: <1990Nov23.161821.21897@kth.se>
Source record: 49814

Hello Networld!

As a hardiskowner I often find it very irritating to open two windows every time I want to use my editor, open four windows when I'd like to run another program, etc. So I thought that arranging some kind of a menusystem would be good, and I Ftp:ed several menuprograms, but I found out that they weren't so good either. Every time I want to copy or move a file (as one does from the desktop), I have to leave the menuprogram.

But then I thought, why not write a menusytem that was contained in an ACC.

So, I started programming, and ran into trouble. How do you run a program from an ACC ?

First I tried with shel_write(). Nothing happened. In the documentation I've got, it says that the program will be run after the current application is terminated. But the accessory application never terminates. Then I tried to start another application inside the acc with appl_init, the shel_write, and then appl_exit, but nothing happened.

Pexec() worked with starting a program, but then after terminating and going back to the desktop, everything got weird. The desktop didn't update and all menus disappeared, etc.

And now I wonder, is there a way to start a program from an acc, and then how do I do it ?

Make sure the SHELL environment variable is set correctly.
If it still doesn't work, press CTRL-ALT-F1 before trying to create
the window; the resulting trace output will likely tell you what's wrong.

(This is something that should have been emphasized in the MiNT
documentation; CTRL-ALT-F1 is *very* useful for tracking down mysterious
program failures. Pressing the key once gets reports of failed system calls;
pressing it twice gets a trace of all system calls. Use CTRL-ALT-F2 to
cancel the tracing.)

From: moses@hao.ucar.edu
Message-ID: <9267@ncar.ucar.edu>
Source record: 49815

I have an annoying problem in a program I am writing. I open a
dialogue box then close the box and immediately afterwards do some
VDI drawing (automatically not by hand) onto screen. The problem is
that the closing of the AES dialogue box does not finish before the VDI
drawing begins and therefore the VDI drawing is also erased.
I have tried putting a delay by evnt_timer and by a long for()
loop between closing the box and the VDI drawing. In each case the
closing of the AES dialogue box is also delayed and it still erases
the VDI drawing. Then I thought it might be my wind_updates but after
changing them it did not solve the problem either.

Well, I've seen it in low-rez mode now, too. In mono, what happens is the
video shifter gets set to medium rez, but lineA, VDI, AES, etc., aren't
notified of any change. From low-rez mode, you get the same vertical
division of the screen, only this time, the right half is black. It's really
strange, I didn't think the way memory was mapped would allow something
coherent to be displayed when modes shifted like this, but there's no
scrambling at all.

I did not have that problem but in similar cases - when I wanted GEM
to do its redraws before I do my draws - I made several evnt_timer's
whith timeout 0.

681. ST Sound Chip

Newsgroup: comp.sys.atari.st.tech
Date: 1990-11-26 22:25:42 UTC
From: bill@mwca.UUCP
Message-ID: <1758@mwca.UUCP>
Source record: 49821

Just thought I'd pass along this info...

This weekend I was swapping monitors (I have a rather elaborate setup allowing me to have video tuner, VCR, ST, or 8-bit sound and video come through some combination of stereo, VCR, or composite monitor) and managed to fry my sound chip - at least, the ST was no longer making sound, and the serial communications weren't working properly. Everything else appeared fine, however (though I didn't try the floppy). At any rate, while diagnosing the problem I pulled out the sound chip, and was surprised to see that the computer booted and ran perfectly (of course, no sound, and still no serial). I was surprised that the computer could run without that chip, however.

Anyway, being lucky enough to have a socketed sound chip, I simply swapped it for a new one ($10, B&C Computervision), and everything works perfectly.

682. Need RS232 configuration help...

Newsgroup: comp.sys.atari.st.tech
Date: 1990-11-27 00:30:16 UTC
From: bro@eunomia.rice.edu
Message-ID: <1990Nov27.003016.24863@rice.edu>
Source record: 49824

I am trying to write a program that talks to an RS232 device that needs 600 baud, 8 bit, 1 stop bit communications with all 8 bits used to communicate (i.e., "strip bit" must be OFF).

If I use the control panel to set to 600 baud, 8 bit, 1 stop bit, strip-bit off, all goes well. But I want to call Rsconf to set this up directly so the user won't need to do it by hand.

I found parameters for everything except the "strip-bit" control. Is that handled somewhere else? If so, what do I need to do?

I tried to trace what the control panel does using a machine language monitor. Besides the Rsconf call, it seems to write directly to RS232 control registers, but that seemed to be just redundant setting of the same things as Rsconf is supposed to set... I certainly could have missed something: tracing machine language execution is nightmarish.

Any suggestions for the missing RS232 calls supported by the control panel but not present in Rsconf? (Besides "strip-bit", there is also duplex, etc.)

Thanks,
Doug Monk (bro@rice.edu)

Strip-bit is redundant, specifying 8 bits/no parity is sufficient. Duplex
is handled by your application, not by the low-level RS232 routines. If you
want half-duplex operation all you have to do is echo everything the user
types.

685. environment in desktop

Newsgroup: comp.sys.atari.st.tech
Date: 1990-11-27 13:49:56 UTC
From: t68@nikhefh.nikhef.nl
Message-ID: <1070@nikhefh.nikhef.nl>
Source record: 49827

Hi,

Can anyone help me with the following?
For an application in the new TOS on the TT it would be
nice if the application can read some variables from the
environment. When an application has been made into an icon
on the desktop the file that is dragged on it wants to
assume that the current directory is the one it came from.
On the other hand the program that lies on the desktop may
want to get additional files from its own directory. There
is only one current directory -> conflict.
The environment would solve this. Hence the question:
is there an official legal Atari sanctioned way to add variables
to the environment of the desktop? The only way I can come up
with is a terrible hack that leaves a little resident job with
the new string. It has to look amoung its ancestors for which one
is the desktop and then modify its pointer to the environment.
If this is the `official' way I would like to know that too,
but it is quite thinkable that there are already better ways.
After all, the new desktop seems to be somewhat ahead of its
documentation (as nearly all programs, except those from ...).

Many thanks in advance

Jos Vermaseren

Are you sure that it is in the ST? I'm assuming that the weirdness is being caused by the multi-sync circuitry of the monitor, since this seems never to have shown up on a non-multisync, and I find it very unlikely that the video circuitry in the ST could 'accidentally' send out each scan line _twice_ on the same line...seems that this would require a doubling of the horizontal scan rate since no information is being lost.

After talking to Talon, the answer to your price/performance question is the Acer. They've tried 'em all. I've seen it, and it's good for the price. The monochrome is sharp, but not as good as the SM124's. The color was good; my Mega-style SC1224 monitor was better, but I've seen worse Atari color monitors than the Acer's color. The problem is that everything is subjective. What I consider to be livable with monochrome could be horror for someone else. I thought it looked all right though.

I settled for a used, year-old NEC 3D. I'm having problems with syncing it, but I called Talon and they recommended that I replace their Omniswitch.

I have collected all if not most of the postings and e-mails to me about multisyncs from here and Fidonet before Nov. 16. If you want, I can arc and uuencode them and send them your way. One guy I know in San Francisco, Dean Brunette, claims that the Sony 1302 is the best for connecting to the ST. He's seen it and the 3D connected to the ST and he still swears by the 1302. When shopping mail order, the 1302 is a little cheaper than the 3D. The lowest I found for the 3D was $579 from Harmony Computers in NY and the lowest for the 1302 was around $539 at another place.

689. MEGA4 internal bus

Newsgroup: comp.sys.atari.st.tech
Date: 1990-11-28 04:29:19 UTC
From: jhp@sactoh0.SAC.CA.US
Message-ID: <4395@sactoh0.SAC.CA.US>
Source record: 49834

Well, I hope this works.
Does anyone have the pin-outs to the internal bus in
the Atari MEGA4? I would appreciate it if someone could
tell me where I could find them. Thanks in advance.

There seems to be no official way to extend the system environment.
You _could_ do it this way: Place some program in your AUTO folder
that links into the exec_os vector. Wait for someone to jump thru
the vector (that is, wait for AES to come up). In this moment,
patch the environment as desired or install a new one.

Unfortunately, this method has been discouraged by ATARI systems
programmer Allan Pratt at the last ATARI Messe in Duesseldorf.
Exec_os seems to be no longer a documented system variable. So
if you do this, it's your own problem if it won't work in upcoming
TOS versions. This is a pity because exec_os is such an extremely
useful system variable, but well...

Maybe Mr Pratt has some better (and official) solution for this?

Has anyone thought about using one of those no-slot clocks in a ST? I just got the JDR Microdevices catalog, and it has these for $30. It says it works in the Apple IIs, IBMs, and any computer with a 28 pin ROM, which the ST has. Does anyone think this could work?

692. Help Wanted: Chicken & Egg Problem

Newsgroup: comp.sys.atari.st.tech
Date: 1990-11-28 19:22:22 UTC
From: ivan@megatest.UUCP
Message-ID: <14555@megatest.UUCP>
Source record: 49830
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

This is probably a ridiculous question; I have been a SW engineer for over a decade, but never used an ST. My brother has one and has used it primarily to run MIDI equipment. Now he has a lot of hardware he wants to hang on to. He wants to do some 'real computer' stuff on his 1040. So much for the intro.

My understanding (from observing this newsgroup for a while) is that there are "UNIXish" pgms out there -- lots of them. Are you people running UNIX? and if so, where did you get it? McGraw Hill is the only place I've heard of. How much is it? Is is 4.2 or sysIV compatible?

Or, am I way off base -- I dunno (AAARGH!). What we do have is the PD version of uniterm. And a host machine (obviously). Therefore we can get some code from the net, but we don't have 'uudecode', 'compress' and/or other UNIX-type stuff you people must have.

And that's the chicken & egg problem we are trying to resolve. Before any of you get upset at such an uninformed question, there appears to be only 2 stores in the entire Silicon Valley which deal in Atari, and I was unimpressed with their assistance (no offense to their knowledge on marketted software). Once we have the basics, I promise to submit more intelligent articles (if any). Please include any archiver info, so we can get a list of what's out there.

Many thanks in advance!

#>Any suggestions for the missing RS232 calls supported by the control panel
#>but not present in Rsconf? (Besides "strip-bit", there is also duplex, etc.)
#
#Strip-bit is redundant, specifying 8 bits/no parity is sufficient.

Nope. I originally did this using the control panel with strip bit on. When reading what should have been chars==255, I got chars==127. With strip bit off, I didn't. If I don't do it with the control panel and only use a call to Rsconf to set 8 bits/no parity 600 baud, I get the same (useless) results: the 8th bit is stripped before I get to see it.

I am using Caux?? calls by the way.

#Duplex
#is handled by your application, not by the low-level RS232 routines. If you
#want half-duplex operation all you have to do is echo everything the user
#types.

This (and likewise with strip bit) is what I originally assumed. Since it was false for strip bit, I wonder if it might be false for duplex as well.

Why does the control panel allow you to play with them if they are supposed to be the responsibility of the application?

So, I still need answers.

Doug Monk (bro@rice.edu)

694. Local Atari Users Group - December Meetings

Newsgroup: comp.sys.atari.st.tech
Date: 1990-11-28 21:41:40 UTC
From: daroloso@aftermath.waterloo.edu
Message-ID: <1990Nov28.214140.16258@aftermath.waterloo.edu>
Source record: 49832
Cross-posted to: uw.sys.atari,comp.sys.atari.8bit,comp.sys.atari.st,comp.sys.atari.st.tech

The Kitchener-Waterloo Eight Sixteen Thirty-two (KWEST) Atari user group,
has a separate 8-bit meeting and 16-bit meeting.
We meet monthly, have special interest groups (SIGs), associated bulletin
boards, public domain libraries, and a newsletter "The Hard Copy".

I am on the executive of the group
so I should be able to handle most questions or
get replies from the rest of executive.

The group welcomes new members and visitors with
8-bits, 16-bits, or those just curious.

Meetings held at the University of Waterloo in the
Math & Computer Building.

Rooms open at 7:00 pm. Meetings start at 7:30 pm.

Call 579-3695 for details.

Next Meetings
****
8-bit - Wednesday, Dec 5, 1990
MFCF Lounge, Room 3012 (3rd floor)

16-bit (ST) - Wednesday, Dec 12, 1990
DCS Course Room, Room 2009 (2nd floor)

Hope to see you there,
Dani Roloson

>Robert Lee
>robertl@locus.com

I believe that's all you do. I'm thinking of selling my 1040ST, and maybe picking up a 1040STe to do so (at least the memory upgrades should be cheaper, plus the advantages of stereo, TOS 1.6?, etc). Though there is someone local to me that supposedly can install a SIMM board into my 1040 for $100-150 (not sure what price). But the use of SIMMs should make life MUCH easier to upgrade...

>one in is probably pretty easy.
Won't suffice, unfortunately. Pin 17 and pin 18 of the second drive
control connector are connected to ground, which makes reading from
the second drive impossible. You have to clip off one resistor, leading
from pin 17 to ground, and remove the connection of pin 18 to ground on
the lower side of the controller motherboard. You'll also nead special
driver software that's aware of the second drive. AHDI won't work.
I don't know if the ICD driver will help you, but I think you'll
at least have to patch it because it looks for special ICD hardware
before running. My driver (CBHD) knows about second drives and works
with all kinds of ACSI hard drives I know, including Megafile 30 and 60.

697. HDX 3.01

Newsgroup: comp.sys.atari.st.tech
Date: 1990-11-29 11:35:03 UTC
From: ralph@laas.fr
Message-ID: <RALPH.90Nov29123503@orion.laas.fr>
Source record: 49836

I have recently recovered HDX301.LZH from atari.archive. The
readme.1st file describes a certain HDX301.ARC, of which this file
seems to be a recompression.

I have an old SH 204 hard drive which uses AHDI version 1. Would it
be advisable to replace my old AHDI.PRG with the new version? Atari's
documentation (readme.1st) only seems to reference megafiles, which
mine is *not*. Do I have to reinstall the the drive? I would prefer
not to reformat the drive! I am willing to upgrade if the new AHDI
is more reliable; it *is* bigger!

From: rfschaa@cs.vu.nl
Message-ID: <8381@star.cs.vu.nl>
Source record: 49748

I have a problem: I have written a device driver for some virtual device. It performs some initialisations, then quits by using the gemdos(49) call (TSR). After a while, when I don't need the driver anymore I would like to free the memory used up by the driver and give it back for general use. Is there any way this can be done?

Richard Schaaf

There was a article some time back on how to do it, as Atari modify
the Controlor, apparently a Adaptec so that you ca't do this, a friend
here did try it with a SH205 some time back and that did not work
each of the drives would work but not both together, if i remember was
some hardware mods..

From: ralph@laas.fr
Message-ID: <RALPH.90Nov29144543@orion.laas.fr>
Source record: 49839
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

I know that this subject has been discussed before in one of these two newsgroups, but I still can't get OPUS to allow me to make charts. I have saved the messages concerning OPUS installation, all to no avail!

I have run ASSIGNER.PRG which built me the ASSIGN.SYS file at the end of this posting. I then used FONTWID.PRG (or some such name). I reboot and OPUS complains about incompatible printer fonts.

I have tried with either my *very* old GDOS.PRG or with AMCGDOS.PRG. This concerns a monochrome system. I have an Epson FX-80 with only a few printer fonts. Is that the problem?

Here's my beautiful ASSIGN.SYS file that was produced by ASSIGNER.PRG:

```
PATH = C:\FONTS\ ;
01p screen.sys
IBMHSS10.FNT
IBMHSS14.FNT
IBMHSS18.FNT
IBMHSS36.FNT

>the VDI drawing. Then I thought it might be my wind_updates but after
>changing them it did not solve the problem either.
>
I don't quite understand this. If I take the phrase "immediately afterwards" literally, it could mean that the screen isn't being redrawn before the VDI drawing is done. When I started with GEM, I was confused between alert boxes (which are erased by having GEM save a copy of what used to be on that part of the screen, and slap it back in when the alert is closed) and dialog boxes (which have to be redrawn by the application). Could that be the problem?

The working difference is in one case, there's an evnt_multi(), in which some event causes the dialog to be used, and when the dialog ends, it falls through to the VDI stuff (WRONG). In the other (RIGHT) case, when the dialog ends, it sets a flag and recycles through the evnt_multi()-controlled loop. Next time through, the flag causes the VDI drawing to happen. Of course, the pending message that a redraw is needed must be handled first. Am I too far off on what's going on here? If the code already takes the correct approach, maybe an evnt_timer(0L) is needed to resynchronize the event handler before the VDI stuff. Or maybe there's a need to wait for a VBL before drawing. What to try next depends on what's been tried already.

Steve J.

I have one in my 520ST. The computer broke (the drives do not work), but
the clock was OK for some time and it is probably.
It worked just like a MEGA clock and is recognized if you have TOS 1.0
or higher.

It has battery backup, sits under one of the ROMs and has two
connections to the processor chip (done by wires with clips on them).
It seems to be exactly the same clockchip as the MEGA has, so I don't
know if it works in an Apple or IBM as well.

This way works very well. I use this method so that my environment
from the desktop matches my environment when I am running from within
the Laser shell. The overhead is insignificant - a 256 byte
basepage plus about 50 bytes of assembly language code plus the
length of the new environment strings. If anyone wants I can post
the example. (This code is not original; I modified it from
code posted to the net about 4 years ago. If I recall correctly
it doesn't use any questionable kludges...)

>There seems to be no official way to extend the system environment.

Ack! don't do that! (I know, atari programming sometimes makes you
jump through hoops. Does it bother anyone else that Gem periodically
resets the trap #2 vector? Like "you didn't reset that for a reason,
did you? Here, let me fix it!")

> Richard Schaaf
> rfschaa@cs.vu.nl

Hmm... TSR... Terminate and Stay Resident... Sounds pretty permanent to me...
Doesn't say, "Terminate and stick around until I decide to free you..." :-)

You can't free memory which has stayed resident as a result of a TSR.
It's not even accounted for in the system as "allocated" memory -- it's
been UNHOOKED from the memory management lists. It's GONE.

Ok !, second time around. My first post a few weeks back received no replies. SO!, I'll try again.

Can any one out there who has any knowledge on ST hardware shed some light on how the the Atari DMA port is converted to SCSI capability.

I don't need the info for commercial profitability, just to satisfy my hacking curiosity. If this is a closely guarded secret, only available to developers, then tell me. BUT if its not, can anyone help. PLEASE !!!!.

710. Need help with windows

Newsgroup: comp.sys.atari.st.tech
Date: 1990-11-30 12:52:09 UTC
From: D.M.Johnson@newcastle.ac.uk
Message-ID: <1990Nov30.125209.13531@newcastle.ac.uk>
Source record: 49750

Okay,
This may sound a bit basic but I still (after trying several times)
can't get the windows to open correctly (well I lest I think so):

What I do is this

```
------------

main()
{
int pipeid,handle;

pipeid = appl_init();
handle = wind_create(NAME,x,y,w,h); /* replace with window coords */
wind_set(handle,NAME,"test",0,0); /* this might be the wrong syntax but I
don't have a problem here */
wind_open(handle,x,y,w,h);

....etc...
--------------
```

So I can get the title bar to appear and the outline of the window. What
I would like to know, Have I missed anything out when setting up the
windows as the background in the window is grey (I use a high rez
monitor) and not the white which I was expecting.

Any help, tips, general comments most useful

Dave Johnson

I was wondering if anyone has used the SUPRA HD interface with a Quantum Q280 80Mb SCSI drive. I have version 3.something of the formating software. Does anyone know the most current version and what drives it supports.

As a side note: I was looking thru the Tech Specialties catalog and I noticed that it said something about a Mega slot uprgrade for the ST. Anybody see or hear about this thing?

> properly through the parallel port?
> -pete

Hi Pete,

There's a "dummy-up" switch on the back of the Centronics ThinkJet that turns it into an Epson-compatible. It's one of the 8 DIP switches, number 4 or 5 if my memory serves me.

The ThinkJet has two operating modes: PCL (or "HP mode") in the book, and Epson (or "Alternate mode") in the book. The Epson mode works fine, except that the dot spacing is 128dpi. Graphics works fine; it's just 25% (33%?) smaller than you would expect.

Now, whether it works with MacPrint is another story!

>>
>>[has a problem with dialog boxes]
>>
>[replies mentioning evnt_multi() and evnt_timer() and even VBL]

From my experience, the sequence goes like this.

1. Build the dialog box via a RCS-like prog or by hand
2. Center it on the screen with form_center() [or if you want to, fill in the x,y,w,h fields in the structure manually]
3. Call form_dial(FMD_START, ...) to reserve some screen space
4. Call form_dial(FMD_GROW, ...) to draw a growing box [optional]
5. Call objc_draw( ) to actually draw it on the screen
6. Call form_do( ) to let the AES handle the dialog.
7. When you get control back again, call form_dial(FMD_SHRINK, ...)
8. Call form_dial(FMD_FINISH, ...) to free up screen space

This last step sends a WM_REDRAW message to the application that owns the screen space where the dialog box was drawn before. If it is the desktop, then it just gets paster over with green (or whatever colour). If it is your application, then it is up to you to react on on the redraw message to redraw your screen space (window etc) before you do other stuff.

This is more work than I was expecting before I learned a little of GEM, but I find it inuitive now, and I like programming this way.

If what I do is in any way incorrect, I'd love to hear about it. I don't mind learning at all. BTW, isn't Lattice C 5 a pretty good development environment? What do you use instead of make?

715. VDI graphics text and GDOS

Newsgroup: comp.sys.atari.st.tech
Date: 1990-11-30 18:49:09 UTC
From: swklassen@rose.uwaterloo.ca
Message-ID: <1990Nov30.184909.29310@watdragon.waterloo.edu>
Source record: 49755

I am having problems with the use of the v_gtext() call when GDOS is installed. Specifically, I have typed in the example program for this function as given in the MWC manual and it did not draw anything. After ruling out most other causes I decided to remove G+Plus from my system and reboot. The program then worked fine. I then installed GDOS (the Atari version, not the Codehead version) and I got the same problem (hence it doesn't seem to be a G+Plus compatability problem).

Further tests showed that with no GDOS installed, the call to start the VDI workstation (the one for the screen), returns lots of reasonable values in the work_out[57] vector. With GDOS or G+Plus installed this vector comes back as all 0s except for work_out[0] and work_out[1] (the screen dimensions) which are correct.

Is this a standard problem?

Can someone tell me what the correct means of writing text (preferably half-height text) into a desktop window?

(The reason is that I am trying to write a csh like CLI which can be run as a desk accessory. My goal is to be able to access my development environment directly from the desktop, without having to enter msh. I will need a number of utilities to do this properly, but most of them require writing text in windows.)

Any help on this matter would be greatly appreciated.

(PS. I will summarize all the responses I got about installing another drive into my Megafile 60 in a few days.)

I would be very weary of anything that tech specialities produces. I bought two of their "so called" CPU cases for my 520 and 1040. Not only did it take over six months just to get the thing working (They had many lame excuses as to why I wasn't getting the whole product.), but they still haven't given me everything that was promised. (I'm missing a delay timer that was supposed to hold the power off the motherboard until the HD's powered up.) I gave up on them after many phone calls and much long distance $$$. Stay away from them. They will give you a massive headache if you deal with them.

>will give you a massive headache if you deal with them.

I bought a memory upgrade for my 1040ST (2.5MB) from them about 2 years
ago. The documentation must've been written by a hacker subscribing
to the rule "if it was hard to write, it must be hard to read".
Anyway, by reading between the lines, and half-guessing, I installed
it myself. Unfortunately I didn't follow their advice, and did not
disconnect the old RAM :-(. After a month of correct operation, the
memory started going flakey. I took it to my local dealer, who
proceeded to disconnect the old memory, and discovered 2 bad
1 Mb chips (which apparently croaked while "fighting" with the old RAM).
He replaced them, and ever since I had a rock-solid 2.5MB.

So I guess the moral is that their product was (is), in effect, good,
and only because of my stupidity I had to do some extra work.
So in all fairness, one can't just generalize and write them off as
bad guys...

On the other hand, I agree that their Customer Support leaves much to
be desired. I remember having trouble getting some additional info
from them. But if enough people complain to them, I'm sure they
would try to improve in that area...
I am not trying to make excuses for them, but it just seems to me that
the ST needs developers. If they're gone, the ST will die.

While on the subject, I might as well give my vote for the lamest, LAMEST
AtariST product ever. It is, by far, the UCSD Pascal system from Pecan.
They won't answer any questions after your Customer ID has expired
(90 days, I believe), and the bloody thing doesn't even work !
$200 for 5 single-sided disks, what a bargain :-#.

Now THEY are the ones who EARNED THE RIGHT to be boycotted.

722. Re: Need RS232 configuration help...

Newsgroup: comp.sys.atari.st.tech
Date: 1990-12-01 16:08:36 UTC
From: kloppen@gmdzi.gmd.de
Message-ID: <3656@gmdzi.gmd.de>
Source record: 49762

bro@eunomia.rice.edu (Douglas Monk)

asks for a Rsconf call for 600 baud, 8 bit, 1 stop bit communications
with all 8 bits used and 'also duplex'.

I'll try to explain, what i'm using in my programs:

The parameters of Rsconf (XBIOS) are
baud (speed)
ctrl (XON/XOFF = 1)
ucr
rsr
tsr
scr

ucr,...,scr are registers of the MFP68901.
The bits of ucr (USART Control Register are here of interest:
Bit 0 : unused
Bit 1 : 0 = parity odd
1 = parity even
Bit 2 : 0 = no parity (ignore bit 1)
1 = parity
Bit 3,4 : length of start/stop bits: 4:0 and 3:1 for both 1
Bit 5,6 : wordlength (only data bits)
6:0 and 5:0 for 8
6:0 and 5:1 for 7
Bit 7 : 1 for async.

If you put it together, you should have:
for 7E1: bin 10101110 oct 256 hex AE
for 8N1: bin 10001000 oct 210 hex 88

the other registers should be unaltered, set to -1.

If that does not work, you have to search on another place, not at the
RS232 interface.

Now 'duplex'/'halfduplex':
This is a feature of your line and that normally is duplex.
These words are misused for the property of the connected host:
if it will echo incoming characters or not.
If it echoes, you should read from keyboard whithout echo (Crawcin),
write to Aux what you get, and write characters from Aux to screen.
If it does not echo, simply read whith Cconin or if you want to filter or
alter the keyboard input, read with Crawin and write to Aux and screen.

From: psurge@cs.utexas.edu
Message-ID: <15308@cs.utexas.edu>
Source record: 49763

I was looking through my ST internals book, and fond an (X?)BIOS routine to write a boot sector on a disk. Now, if anyone read (and hardly anyone replied) my last post about my boot sector on the HD crashed and I wanted a program to rewrite my boot sector.

What I want to know is is it possible to write a program (hopefully in Personal pascal because that is the only language I have on floppy, my Sozobon C was on the hard disk!!) that will ask for sizes and the like and pass all the appropriate parameters to this routine. (Ok, I know that can be done) BUT, will I get a boot sector on my Hard Drive, or does this routine only work on floppy disks.

Sorry I cannot tell you the routine name, I am not at home with my ST Interals book. However if there is confusion and those "in the know" do not know what routine I am refering to, then I will post the procedure name when I get home, if someone asks about it.

For those who do know what I am talking about, what parameters do I need to pass for this routine to work. The book only discusses the use of Floppy disks, But I need to know for my Hard Disk (20megs, 4 partitions).

AS long as they are as Fast or Faster than 150ns they are OK, also you can use 9 or 8 bit SIMMS, the STE uses 8 bit SIMMS, but if you wish to sell them, 9 bit one would be better, here in NZ. 8 bit simms cost a lot more, they don't sell as many as PC. ones...

Hello Ed,

On the STe the modified DE-signal resides only *inside* a chip. So there is no chance for an STe / TT / MEGA-STe OverScan :-(

But i have some other good news : The english manual's / master disc is ready! The first 100 pieces are send to GB on monday. In germany we have sold about 2100 overscan hardwares. Up to now we have done absolut NO advertising! It realy sells without :-) The first 'english' review is in the 'ST-World', i haven't yet seen the article, but our british distributor was very happy about it. We also got french and italian distributors, i hope USA, Canada and Australia will follow...

Greetings, Karsten

After openning the window with window_open, you should get a message WM_REDRAW, telling you to draw the content of your window. The AES only draws the frame of the window, and it is your own responsability to fill it with whatever you want. Anyway, as far as I remember, the first parameter of wind_create is not the name of the window but the kind of window you want.

730. Mega ST Real Time Clocks

Newsgroup: comp.sys.atari.st.tech
Date: 1990-12-03 16:52:49 UTC
From: ralph@laas.fr
Message-ID: <RALPH.90Dec3175249@orion.laas.fr>
Source record: 49769

What's the accuracy of the real-time clocks that come with Mega STs?
I've noticed that on mine I'm losing a second a day. Is this within
specs? The batteries are fresh.

The real-time clock (ZTime) that I had on my old 1040 ST seemed more
accurate than that.

Any comments?

Maybe my computer is way too fast approaching Einsteinien limits in
its calculations. :-)

From: svrobins@npe.isnet.inmos.co.uk
Message-ID: <138.275aa08e@npe.isnet.inmos.co.uk>
Source record: 49771

Can anyone tell me what I need to upgrade my Mega2 to 4 Megs?. Can I do this by simply plugging/soldering the extra Ram, or do I need to do anything else eg cut/insert links etc.

If anyone has done this job (without an upgrade kit) I'd appreciate any info.

Thanks,

Paul Robins.

>interested in the software since I have a multisync. Thanks.

Overscan can't work on an STe because the signals that Overscan uses
are not available outside the display chip. You'd have to go in with a
microscope and some REALLY SMALL tweezers and wire.

From article <RALPH.90Nov29144543@orion.laas.fr>, by ralph@laas.fr (Ralph P. Sobek):
> I know that this subject has been discussed before in one of these two
> newsgroups, but I still can't get OPUS to allow me to make charts. I
> have saved the messages concerning OPUS installation, all to no avail!

(etc.)

Apologies, folks. I tried mailing Ralph but the message bounced.

I think the problem doesn't have anything to do with GDOS versions. The simplest thing to try would be to make sure there are the same number of fonts defined in the assign.sys file for each resolution as there are printer fonts. Also, the last four characters of each filename in each resolution should match the last four in a printer filename. Below is Ralph's assign.sys file amended so it should work. I've commented out (using ';') the lines which I suspect are causing problems - assuming the printer files listed are valid Epson printer files.

Here's my beautiful ASSIGN.SYS file that was produced by ASSIGNER.PRG:

```
PATH = C:\FONTS\
01p screen.sys
; IBMHSS10.FNT ; I think you have to choose between IBM & ATR files
; IBMHSS14.FNT ; If you keep these, comment out the 10 & 14 ATRs
; IBMHSS18.FNT
; IBMHSS36.FNT
ATRHSS10.FNT
ATRHSS14.FNT
; ATRHSS18.FNT
; ATRHSS36.FNT
02p screen.sys ; I don't think Opus runs in Low-res, so these are
; IBMHSS10.FNT ; all probably redundant
; IBMHSS14.FNT
; IBMHSS18.FNT
; IBMHSS36.FNT
ATRHSS10.FNT
ATRHSS14.FNT
; ATRHSS18.FNT
; ATRHSS36.FNT
03p screen.sys
; IBMHSS10.FNT
; IBMHSS14.FNT
ATRHSS10.FNT
ATRHSS14.FNT
04p screen.sys
; IBMHSS10.FNT
```

```
; IBMHSS14.FNT
ATRHSS10.FNT
ATRHSS14.FNT
21 FX80.sys
EPSHSS10.FNT ; If you had more fonts here, you could have more
EPSHSS14.FNT ; screen fonts
31r META.SYS
```

Message-ID: <1990Dec4.191655.24027@msuinfo.cl.msu.edu>
Source record: 49777

This has probably been hashed out quite a few times, so please respond via e-mail. If the problem interests you, send me mail and I'll forward solutions I receive.

Here it goes:

I will be using SOZOBON. I want to make a desktop accessory that can call a program.
1.) Is it possible to call a program from a desktop acc?

I have never programmed on an ST before, but have been reading c.s.a.st.tech & c.s.a.st for over a year. I have a VERY ROUGH idea. I think I need to use a resource file for the box that will get all the options for the called program. I am not sure how to
2.) How do I get C code to utilize a resource file?

I would guess that is all for now. My goal is to write a desktop acc to call Sozobon. That way, I don't have to leave my text editor to compile.

Of course, I'll GIVE IT AWAY if it works!

740. Should I buy this Atari ST1040?

Newsgroup: comp.sys.atari.st.tech
Date: 1990-12-04 22:03:48 UTC
From: dlau@sdcc13.ucsd.edu
Message-ID: <14706@sdcc6.ucsd.edu>
Source record: 49785

I've been in the IBM world for about 6 years (I say that to
show my ignorance of Atari STs) and I'm considering buying
a 1040 ST. The deal I've got is:

Atari 1040ST, Monochrome monitor, Magic Sac, Transformer
(or is it Translator? ... it works in conjunction with Magic Sac??),
and some other software, in trade for $150 + Mitsubishi MR535 (new)
+ 3 boxes of Verbatim disks + 6 6-outlet surge protectors.

I don't necessarily need to get the Atari right away, but this
deal won't wait for me. As a programmer, it's very possible
that I'll need to upgrade the memory, and I believe the STe
lets you upgrade to 4 megs within the base system. I may also
need more than 512 colors on the screen, but again, this
is way down the road. However, if this is an amazing deal, I
certainly wouldn't want to pass it up.

My question is, does this seem like too good a deal to pass up,
or is it old enough that I'm better off keeping my new harddisk,
$150, etc.,? In other words, how good a deal is this? Should I
wait for the new stuff? Is Atari going to orphan the ST soon?

Thanks for any input. Sal

741. Talon Omniswitch :^(

Newsgroup: comp.sys.atari.st.tech
Date: 1990-12-05 00:01:09 UTC
From: ekrimen@ecst.csuchico.edu
Message-ID: <1990Dec05.000109.24767@ecst.csuchico.edu>
Source record: 49783

What a piece of garbage! I got my second Omniswitch today because the first one was defective.

The first one wouldn't sync (with my NEC 3D) in monochrome at all. There were a couple of "screens" on top of each other on the right side of the screen. It will only sync in the 60Hz color modes after the monitor has been off for a while. It works fine in 50Hz (when I run a program to change the scan rate).

The second one is worse. I KNEW it wasn't going to work. I get NO monochrome image. It's like the monitor is off. The color image seems to not have the red line connected. The whites are a light-blue and there is never any red on the screen.

On top of it, the tech at Talon (the manufacturer -- if you want to call it that :^(-- of the Omniswitch) is only there from 10am to 1pm. He probably takes a 3 hour lunch from 10am to 1pm too. This really sucks big time.

Hope your day has been better than mine.

(If anyone would be willing to make a switchbox to connect my ST to the NEC 3D, I would very grateful. I don't need the audio, just the video. What's your price?)

if u used microemacs (3.9i or later?) u would not have to leave your editor. since both soz and emacs come with source, u could hack up a system to point yer editor to the offending lines on errors, as well. i think emacs may do this with MWC now, but i don't use that compiler. the spell.cmd command file for emacs may give u some ideas, too.

the gulam shell has emacs built-in as well, and can be "backgrounded".

From: archbold@bluemoon.uucp
Message-ID: <3uwoT1w163w@bluemoon.uucp>
Source record: 49780

I know OPUS spreadsheet has probably been discussed here on numerous occasions, but I got some problems and there might be people out there willing to help

Problem is this: At first, I created my assign.sys file and used regular screen fonts for the printer. FontWid would bomb on me because for some strange reason FatSpeed would screw it up.

After I wouldn't run FatSpeed everything would go OK, and when I tried to print a chart, Opus would tell me that there are differences in font widths and I should report it. It wouldn't do the chart afterwards.

Today my bro got some (supposedly) real printer fonts with matching screen fonts. I was able to load the supposed printer fonts with GEMFED, so I don't really know what the difference is (?). Anyway, when trying to print a chart, the same thing would happen (Opus would tell me that the opus.wid contains names of files which are not width compatible.

Has anybody had this problem? How do you solve it? I tried AmcGdos, GdosPlus, and good'ol GDOS 1.2...

If more info is needed to determine how to solve the problem, I'll provide it.

I have had a go at doing this too. I don't think it's possible without tinkering with the OS pool entries. That of course would be a highly undocumented thing to do and would result in Allan Pratt slapping your wrists heavily.

What I want to write is a temporary RAM disk for use under Gulam.
That way I could have a RAM disk while compiling a C program but throw it away afterwards leaving more memory for the compiled application to play with. Pure joy! Pure fantasy?

I tried some really weird things like re-executing the TSR using Pexec #4 in the hope that a Pterm instead of Ptermres would blow it away on the second run. Another good try was for the TSR to Mfree it's own basepage. The results were either no effect or bomb outs.

Come on Allan, help us out on this one.

There are the Supra Hard Disk Utils that will let you do this
there are A set of the Old PD ones on Genie, also is it not
posible to just reinstall the Booter, I use ICD Utills, and run
there from a Floppy, and just select the Boot option, this installs
the code into the boot sector and the Driver onto the hard disk.
The Supra Utils lets you Read and Write Sectors, plus make the
Boot Sector executable, there is also a util that will backup
boot sectors,partitions, etc. Mirror2 are some thing like that.

Message-ID: <1990Dec5.102405.1@simvax.labmed.umn.edu>
Source record: 49643

With regard to Opus 2.2 ...

There appears to have been a problem in the GDOS font definitions for the Courier (aka 'typewriter') fonts. Evidently the font descriptor indicates it is a 9-point font, while the font title indicates is is a 10-point font. Two fixes were suggested: (1) modify the font file using a hex editor or (2) removing mention of the Typerwriter font style from ASSIGN.SYS. I chose the latter, and the font-width program supplied with Opus had no problems since.

(The GDOS fonts I have were probably from WordUp ... I have the original Atari release via the Toolbox for Personal Pascal, and have had DEGAS Elite and other sorts of GDOS fonts and drivers from various software packages since, so I no longer can be sure where the fonts are from...)

>mine is *not*. Do I have to reinstall the the drive? I would prefer
>*not* to reformat the drive! I am willing to upgrade if the new AHDI
>is more reliable; it *is* bigger!
>

Hello Ralph!

You can use AHDI 3.01 with your SH 204, but you must reinstall the drive.
I would advise you to do this, because the old HDX versions can't detect
bad blocks on the drive correct. Another advantage from AHDI 3.01 is, that
you can use more than four partitions on one drive and that the partitions
can be bigger than 16MB. So you can use your 20MB completely for C:.

For installing the new AHDI you must use HDX for reformating and partitioning
your drive. The wincap-file for my HDX knows the SH204. If your copy doesn't
know it try SH205 or MEHAFILE 20 instead. After that procedure you can
install the new driver with HINSTALL.PRG so that AHDI can be booted from HD.

Greetings, Olaf

753. Disk Drive Problem

Newsgroup: comp.sys.atari.st.tech
Date: 1990-12-05 18:14:34 UTC
From: mcli@joker
Message-ID: <10805@ur-cc.UUCP>
Source record: 49642

Hello everyone,

I have a 1040ST with an internal double sided drive which seems to have an interesting problem. One day, I found out that it couldn't read any of my disks except for a couple. So, I downloaded some utilities to my hard drive and did some tests using disktbox. First, I would put a disk into the drive and double-click on the drive A icon. this would get me a dialog box saying that the drive isn't accessible. then, I would use disktbox and read the boot sector of the disk, and it would read fine, then I exited and double-clicked on the drive icon, and I would be able to get a directory of the drive and the files on it were ok! However, running a scan a few times on the disk would display bad sectors inconsistently.

So, I ran a drive speed program to see what the speed of the drive is. It was something like 304.56rpm. As I recall, the speed should be around 300rpm. Could this be my problem?

If the only solution is to replace the drive, I would like to find out which drive mechanisms work the best, and where to get them. Are there any other solutions?

Please email to me, and I will summarize if there is any interest.

Thanks,

Maurice

- out which drive mechanisms work the best, and where to get them.
- Are there any other solutions?

I've never looked at a floppy drive mech that well, but I hear that
there should be a pot on some that allow you to adjust the speed of
the drive. Try this first. (Also, if possible, try the disks on
another ST.) Ask the net for info about adjusting the drive speed.

From: emerson@gandalf.Berkeley.EDU
Message-ID: <39913@ucbvax.BERKELEY.EDU>
Source record: 49650

Apparently some Mega 2s were made w/o space on the mother board
for a extra 2 megs (most were) If you have the holes just add sockets
and (and 3 resitors, probably 68 ohm[some already have the resistors \
))

Otherwise you need a clever soldering iron or a 3rd party board.

On an unrelated note, I'd like everone to send me the plans on how to
hook up a IBM mouse to an atari. I have a PS/2 mouse, however any detailed plans on how to hook up
either the bus or serial mouse to an Atari would be very apprciated

Thanks
a bus or serial mouse to an ST would be greatly apprciated.

> And that's the chicken & egg problem we are trying to resolve.

Would it be an idea if there was a 'starter pack' available on an FTP site
(e.g. Atari.Archive)? This could consist of uudecode / arc / lharc / zoo
etc. and be in the form of a self-unpacking archive. Thus, when this was
downloaded, the 'chicken & egg' situation would be resolved.

If there is any interest, I'll make one up and upload it.

Could be.

>If the only solution is to replace the drive, I would like to find out
Some drives have a small potentiometer inside for adjusting the speed.
While the rpm program is running, adjust the screw until the program says 300
RPM.

>What I want to write is a temporary RAM disk for use under Gulam.
>That way I could have a RAM disk while compiling a C program but throw it
>away afterwards leaving more memory for the compiled application to play
>with. Pure joy! Pure fantasy?

I wrote such a ramdisk some time ago and use it regularly. The ramdisk program consists of two parts: a small resident driver and a configuration program which allocates and frees memory for the ramdisk. To keep the memory from disappearing when the configuration program exits, I change the current process pointer (a documented system variable in low memory) to another value before doing the Malloc and restore it to its old value immediately after. (I think I set it to the basepage of the driver program, but I might be using the basepage of the desktop or some other process that isn't likely to go away.) This causes Gemdos to think the allocated memory "belongs" to the driver instead of to the configuration program and hence it won't be freed automatically when the configuration program terminates.

This method of allocating persistent memory works under TOS 1.4. However, I don't think it is officially approved for the user to write to the current process pointer, so this scheme probably isn't guaranteed to work under future versions of TOS. (I also don't recall whether or not it works under older versions of TOS.) Unfortunately, I don't know of any way that IS officially sanctioned to allocate and free resident memory.

I should point out that another problem one faces is memory fragmentation. Memory is allocated and freed in blocks. If one allocates blocks A, B, C in that order and then frees block B, there will be a "hole" in memory between blocks A and C. Free memory has now been split into two pieces, the hole and the rest of memory after block C. Whether or not the memory in the hole is useful depends on how big it is and how large the blocks are that are needed in the future.

Message-ID: <1990Dec6.210124.4977@udcps3.cps.udayton.edu>
Source record: 49648

In a very fruitless search for memory upgrades for my brother's old style 520ST, I come to this group for help. He wants to go from the 512K (standard) up to 1024K. Using upgrade boards, about the cheapest either of us has found it is $260 (including installation). Since all he will ever want to go up to is 1024K, so do you know of anyone who still does the upgrades by piggybacking the chips? I know that before the advent of all of these memory upgrades, that's how it was done, but none of the locals will do it anymore. Does anyone know of someplace that will do it?

Thanks!
Jim

I am very interesed in this as I am about to go through a similar
exercise for different reasons.

>I would guess that is all for now. My goal is to write a desktop acc
>to call Sozobon. That way, I don't have to leave my text editor to
>compile.

I don't leave mine now. I use MUPFEL as a shell and elvis as the
editor. The sequence :!make is all I need to compile.
You could do it with GULAM also by temporary leaving the editor with
^Z then typing whatever you want at the command prompt. fg will
return you to your edit.

>bad blocks on the drive correct. Another advantage from AHDI 3.01 is, that
>you can use more than four partitions on one drive and that the partitions
>can be bigger than 16MB. So you can use your 20MB completely for C:.

You don't have to re-format or re-partition the drive to take advantage
of the new driver. You do have to run HINSTALL from the new
distribution: it will re-write the root and boot sectors in addition to
copying the new driver to the disk.

On the other hand, you do get some advantages when you reformat with 3.01.
As Olaf said, you can have partitions greater than 16MB, and more than four
per drive, but in addition you get better bad-sector tracking. Besides,
isn't it time for a full backup anyway? :-)

By the way, 3.01 won't let you repartition an old-format drive without
reformatting. Just so you know.

I'm sure, that every multisync monitor can work with ST.
I have the NEC 3D, and I see no reason why xD (x>3) wouldn't work.
About 2A, I have a cable to connect ST to NEC 2A, I don't need it.
It is made by LINDY, I have bought it from Germany. But it is quite
easy to make a cable for a monitor, IF you have the pin assignments
(can be found from manuals), IF you can get the proper connectors
(ST's 13-pin round is a problem, cut from old cable).

I think the german ST technicians are resourceful enough to overcome this one.
Why not just remove the video chip and replace it with a board which provides
same functionality and some extra resolution / colours / etc.
It might take a little longer but it can be done, wait and see.

How to install EDISK.
An introduction and guide for the novice.

by
Leroy J Dickey

Have you ever tried to copy several files from one floppy to another,
and discovered that you have to pop your floppies in and out of the
disk drive until your arm gets sore?

Would you like this job to go a more smoothly, so that you read all the
files off the floppy drive in one step, and then swap floppies and copy
the files to the new drive? Well, have we got a deal for you. You
need a ram drive. This nice piece of software organizes some of that
abundance of memory you have on your system into something called a RAM
DISK or ram drive. A ram disk works in every way just like a floppy
drive, with two exceptions: (1) it is much faster and (2) it is
volatile (it goes away when you turn you system off). However, it does
not have to go away when you do a "warm boot" by just pressing the
little button on the back of your ST. So what's the catch? Why didn't
the system come set up with one of these wonderful little babies? The
answer is that it uses memory, and you might prefer to use the memory
for running a game or TeX or something else.

I have heard some advanced users express the opinion that
now that they have a hard drive, they no longer need a ram disk.
Maybe they don't, but I do. Not so much for copying floppies as
I used to do, but for fast response when I want to combine several
commands into one, and these commands involve some step in
the middle that requires the use of a temporary file. I want
that file creation and writing to happen quickly, and I want the reading
of the file in the following step to also happen just as quickly.
With a ram disk, I don't have to wait for the physical medium to
respond. I don't have to wait for the little arm with the little head
on it to position itself over a spinning disk, and I don't have to
wait for the disk to spin into position, and so on. Just as the
hard drive is about 10 times faster than the floppy drive,
the ram disk is about that many times faster than the hard drive.

There are a number of ram disk programs around. I think that one language
vendor included the source code for a model ram disk program for
novice programmers to practice with. This means that many beginning
programmers have written their idea of a ram disk program.
However, one of the best ram disks around is EDISK, version 2.1,
by Volker A. Brandt, of the Department of Applied Mathematics in
Bonn, West Germany.

It is, unlike lots of other ram disk programs, small and fast. I think this means that it is written in assmebly language, becuase of its very small size, with fewer than 800 bytes. The size of the resulting ram disk can be configured from 10K to 3900K, it is reset (warm boot) proof, and it is said to work on the 520, the 1040, the Mega ST, the STe. EDISK is free. I got my first copy by e-mail. It is available from the "terminator" archive, "atari.archive.umich.edu", or, if you are a member of KWEST, you can get it from the KWEST library.

I have been using EDISK, version 2.1, on my Mega ST2 for several months now and, as far as I can tell, it works flawlessly.

How to set up EDISK on your system

I know from experience that changing programs in the AUTO folder can be trying, to say the least, and so, for the complete novice, I list steps that will lead to successful installation of a ram disk.

If you already have some experience in this regard, you may be able to read between the lines and see some short cuts, but for the complete beginner, the steps I outline works for me and has worked for others.

- If you already have an AUTO folder,
copy the files in it somewhere else, say to AUTO.OLD
and delete AUTO and all the files in it.

- Make a folder called AUTO.

- Copy EDISK21.PRG and ECONF21.TOS into AUTO.

- Run (double-click on) ECOF21.TOS to configure the EDISK21.PRG file and:
select size (350 is about enough for a single sided floppy).
select a letter for the name of your ram disk (I recommend P).

- Cold boot:
Turn off the power switch for your system.
Turn your system back on.

- A short message about EDISK21 should flash across the screen.

- On the desktop, click once on any drive icon (A will do).
The icon image will change (reverse video).

- Point to the pop-down menu for "Options" and select "Install Disk Drive".
Use your arrow keys to move arround, and
Change the drive letter from A (or whatever it is) to P (the
same as you chose above).
Change the drive label from "Floppy drive" to "RAM DRIVE".
Click on INSTALL.

- An icon for drive P should appear on the desktop.

- Double click on the P icon and get a window for you new ram drive.
If this window appears you have done it. You are the proud owner

of a ram disk.

- Move your icons to the places where you want them to be.

- Put the P: window to where you want it to be.

- Open any other windows you like and position them where you want them.

- Again select the pop-down menu for "Options" to click on "Save Desktop".

- Try a cold boot again, (power off, power on) just to see if
everything is working. This time the window for the Ram Drive should
appear on your screen.

- If so, I recommend copying the AUTO folder and DESKTOP.INF to a
clean floppy and keep this as a backup.

- If you have any files in AUTO.OLD, copy them to AUTO.

- Cold boot agian. If all is working correctly, remove AUTO.OLD.
If not, move back to a stage where everything works.
For instance, copy the directory from your backup floppy, and try some
variation.

- Have fun.

I have not written everything there is to know about EDISK, but it
everything you need to know to get started. After you have used it for
a while, you might want to know how to turn it off. This it is
possible to do, and the documentation that comes with EDISK tells you
how to do it. EDISK has other nice touches. For example one of these
it that it creates the ram disk with a volume identifier. This is not
especially significant most of the time, but if you have a program like
"lc" (yes the famous Waterloo "List Catalog" program has been ported to
the Atari), it shows the volume identifier, before it shows the
directories, followed by the files, and the hidden and system files.

All in all, I give this little gem a very high rating. It does
everything it is supposed to do, and to the best of my knowledge does
not interfere with the running of any other program, with the exception
of the necessary fact of life that it takes up some space.

Unless someone shows me a Panasync working on an ST or tells me of one working on an ST, I will believe that it does not. It doesn't sync low enough to work in the color modes. This is the 1381. The 1391 may be a different story. I didn't think that it had analog input, which is required for it to work on the ST, but Keith Gerdes mentioned that it's cable can detect digital or analog; I'm not quite sure -- perhaps he can explain it to us. Keith?

BTW, I'm using an NEC 3D.

776. Reading the timer

Newsgroup: comp.sys.atari.st.tech
Date: 1990-12-10 09:54:31 UTC
From: alex@hpgnd.grenoble.hp.com
Message-ID: <17750001@hpgnd.grenoble.hp.com>
Source record: 49666

Hello there,

1)
Does anybody know if there is a way (should I say official ?)
to read the system time of the 520STE that will give a result
more precise than 2 seconds intervals.

The Bios or Xbios call GetTime() only returns hours,minutes, and
seconds divided by 2 (ie from 0 to 30).

I need something much more precise than that. Any idea?

2)
What Xbtimer() xbios call is supposed to do ?

Thanks,

alex.

777. Deskaccs with GCC

Newsgroup: comp.sys.atari.st.tech

Hi there,

Now that I have my Gcc cross compiler up and running on my Sparc station, I would like to compile the sources for a deskaccessory that I wrote. Standard compiling:

gcc -o foo.acc foo.c -lgem

does not seem to work, since my ST then just reboots when it tries to load the accessory. I assume that for accessories I need a different startup module (?). Can anybody tell how to do this (I don't see accessories mentioned at all in the GCC docs).

Disclaimer: Despite of this, GCC is still the greatest thing since sliced bread!

I agree wholehearedly with Leroy J Dickey's review and guide. I add that it is based on the famous ETRNL2 By Mr. Franco, but that it has been completely rewritten, debugged, and improved. I had to move up to it when I got my Mega 4 ST.

My only comment is that you have to deconfigure it if you do *not* want a RAM disk! I preferred good ol' ETRNL2's possibility to disable with ALT-something-or-other. Sometimes one just needs all the memory that one can get, and only for a short while. Having to use EKILL.PRG is, to me, cumbersome. Volker A. Brandt, are you listening?

Otherwise, I just love it! Use EDISK 2.1!!

Message-ID: <2221@ncrcam.Cambridge.NCR.COM>
Source record: 49667

I have several macros that og me into several different systems. Until last week everythinig was great. Then I had to get into a system that has a different baud rate and number of data bits. Well I have been making those changes manually as I change between systems. I want to include those in my login macros. According to the documentation that I have, the function that I want to use is RS232CONF. So far so good. DOCs say to see dialer setup for description of the configuration string to supply to RS232CONF. O.K. I found that. The two strings that I want appear to be 10001 and 20101. But I cannot get Uniterm to accept these. I have tried several different formats as follows:

```
rs232conf(10001)
rs232conf('10001')
rs232conf('/10001')
rs232conf(/ 10001)
rs232conf('/ 10001')
```

None of these do anything except abort the macro processor. Can someone tell me the correct format that will make my life a whole lot easier? I hope so.

780. 520 ST Memory upgrade.....

Newsgroup: comp.sys.atari.st.tech
Date: 1990-12-10 16:54:42 UTC
From: Yonderboy@cup.portal.com
Message-ID: <36772@cup.portal.com>
Source record: 49672

Well I tried to send this to 2 people and it bounced both times.. So, I'm just going to put it up here... A friend of mine has done this upgrade and it seems to work fine... Do desolder the caps as it meantions:
Atari ST Memory Chips

Jeff Rigby / SOTA Computers
3949 Sawyer Rd. Sarasota, Fl.

The following is a brief overview of the Dynamic Memory used in the ST series of Computers. Provisions were made in the design of the Memory Management Unit for 64K (4164), 256k (41256) and 1meg (411001) chips.

The Memory Management Unit does a variety of jobs in dealing with the memory, all these are transparent to the 68000 MPU. Dynamic Ram is currently the most popular memory used in computers today, it is very inexpensive and reasonably fast. The bad news is that it has to be refreshed every 4ms or it looses it's memory. Refreshing is accomplished by strobeing all the Rows in the multi-plexed memory. In computers without a MMU the MPU looses up to 20% of it's time in just doing refresh. The great news is that Atari designed the ST with no wait states. The MMU does the refresh and Multi-plexing of the dynamic ram and the CPU (68000) is free to do what ever is needed. The MMU can controll two banks of two 8 bit words each. The current method of determining the amount of memory uses an 8 bit byte as it's base. In other words, 8 bits * 256K = 256K bytes of memory. In the ST we have 16 bit words 2*(8bit)* 256K = 512K bytes of memory in one bank using 256K chips; with two banks you have 1 meg (this is the one that will be added).

Using the new one meg chips you have 2*(8bit)* 1meg = 2meg byte per bank. If you are going to upgrade your memory then replacing one of the 512K byte banks of memory with 1 meg chips gives you 2meg plus what you have in the other bank for at least 2.5meg bytes.

41256 4 - CMOS very low power (runs cool)
1 - 1 bit
256 - by 256K

top
|-----|
A8 1 -| |- 16 Vss
Din 2 -| |- 15 CAS/
WE/ 3 -| |- 14 Dout
RAS/ 4 -| |- 13 A6
A0 5 -| |- 12 A3
A2 6 -| |- 11 A4
A1 7 -| |- 10 A5
Vcc 8 -| |- 9 A7

|_____|

A0-A8 Address lines
Din Data in
Dout Data out (on the ST the data in and out are hooked together)
WE/ Write enable when this line is low
RAS/ Row Address Strobe
CAS/ Column Address Strobe
Vss Ground
Vcc 5 volts

Refresh and RAS are accomplished when the RAS line is held low and the proper row address is selected. Refresh requires that all 256 rows be addressed one at a time. The RAS line is held low and a number (base 2) is put on A0-A6, the address bus. This is done 256 times (one for each address).

Writing to Memory is done by:

1) bringing RAS low
2) put the proper address (row address)on A0-A8
3) bring RAS high
4) bringing CAS low
5) put the proper column address on A0-A8
6) bringing CAS high
7) bringing WE low
8) put data on Din
9) bring WE high

Reading Memory is done the same way but use Dout in step 8.

As you can see there is a lot that the MMU has to do, it is running at 16Mhz doing the calculations for the Multi-plexing and other functions, but the Memory it's self can only be addressed at 4 Mhz due to the speed restrictions in CMOS devices.

The chip that is in your ST now is a 41256 dynamic ram memory chip; the one meg chips you may have heard about are still too expensive but they will come down in price soon. When they do you may upgrade your computer to a 2.5meg byte or 4meg byte ram system.

411000 4 - CMOS low power (due to improvements this chip runs 20% faster than 41256)
1 - 1 bit
1000 - by 1000k

Vcc 9- | |- 10 A4
|_____|
```

If you will notice there is an A9 pin on the DRAM that was not on the 256K chip, this is where it gets the extra address range. The A9 pin on the MMU is not connected to anything in the ST and as you notice the pin configuration of the 1meg chip is nothing like the 256K chip so to upgrade I guess I am going to have to make a PC board to hang on the mother board of the ST. The refresh and addressing of this chip are the same as the 256K chip with the exception that refresh is done on 1000 addresses and the row and column addresses are 1k by 1k.

The ST is one of the best designed personal computers on the market. We hear of all the co-processors in the Amiga but never hear of the co-processors in the ST; there are several of them including several DMA channels. Atari just doesn't blow it's own horn loud enough. Did you know that in all most all tests the ST is faster than the Amiga or the Mac. The memory upgrades to the Amiga slow down the Amiga 12% (refresh is not transparent). Upgradeing the ST is very inexpensive and very expensive on the Amiga or the Mac. Atari went to great expense to make the ST VERY UPGRADEABLE, for our benifit and theirs (they wanted several new improved models to sell later).

I have brought this over un-editted from the arpanet info-st mailing list. I TAKE NO RESPONSIBILITY FOR ITS CONTENT OR ACCURACY. I HAVE NOT TRIED THIS MODIFICATION ON MY OWN ST AS YET. I AM PASSING THIS ALONG TO THOSE WHO DO WISH TO TRY IT. FOLLOW THE DIRECTIONS AT YOUR OWN RISK.
--Dwight McKay (75776,1521)

From: gert@pescadero

WARNING: This is a hardware modification that will void the warranty of your 520ST. If you do not have the appropriate tools or experience you have a substantial chance of ruining your 520ST. Proceed at your own risk! This modification has been in my 520ST without any problems for 6 days now. However, I have (of course) not checked with knowledgable sources at Atari to verify if this modification endangers the long term machine reliability and/or software compatibility (I suspect it may endanger their software compatibility if enough of us do it!)

Tools & components needed :

16 256K * 1 RAM chips, 150 ns access time type, e. g. NEC 41256C-15 (avilable at e. g. Fry's Electronics, Sunnyvale, CA for $2.77 each)

A good quality, preferrably temperature controlled soldering iron, with a minature tip (tip should be narrow enough to avoid touching 2 I. C. pins at the same time) e.g. Weller type soldering station.

Good quality resin core solder (thin).

Approximately 4 foot of wire-wrap wire and a good stripper for it. (you will have to route 3 wires over a sequence if I.C. pins. The easiest way to do this is t have a stripper allowing you to shift the insulation forward over the wire, solder the next point, measure new length, shift over insulation, etc. until the endpoint). The "No Nik" 0.014 (dark green handle) wire wrap stripper is the best tool for this. Available e.g. at Jensen tools, Phoenix, AZ (602) 968-6231 catalog no. H4B305.

Desoldering wick and solder suction tool.

Philips type screwdriver (for opening your ST), tweezers, pliers, etc.

A steady hand and self-confidence.

Explaination of the modification :

(Please read the rest of this document before starting. It may save you time and an 520ST)

The current memor inside the 520ST consists of 16 256K*1 RAM chips. Address (A0..A8) lines are common to all those chips. The Write Enable line is also common to all chips. Data (in and out) lines are of course individual. The RAS (row-address strobe) line is common to all chips. The 8 chips forming the high order byte group have one common CAS line, and the 8 forming the low order byte group have one common CAS line (CAS is used as enable for write operations, such that Write Enable can be common to both groups). The high order group from MSB to LSB consists of U45, 44, 43, 42, 38, 34, 33, 32. The low order group of U30, 29, 28, 25, 24, 28, 27, 26. Note that all chips are adjacent, though the numbering has gaps. RAS0, CAS0H, and CAS0L are supplied from U1 pin 8,6 and 7 respectively (the 0 indicates bank 0).

Bank 1 that you are going to build in will be "piggy-backed" on top of the current chips, where all pins of the new chips EXCEPT RAS (pin 4) and CAS (pin 15) are soldered to the old chips equivalent pins. Thus they will end up sharing addresses, data, Write Enable and power and ground with the existing chips.

All RAS pins of the new chips are wired together and will be supplied with the "RAS1" signal generated on pin 18 of U15 (the memory controller, marked 3H-2119C or so). The CAS pins of the 8 new high order byte chips (on top of U45..U32) are wired together and supplied from the "CAS1H" signal generated on pin 22 of U15. Analogously, the CAS pins of the new U30 to U16 are wired together and supplied with "CAS1L" from pin 21 of U15.

How to go about it:

Step 1: Open up your 520ST, pull off the keyboard connector and remove the main circuit card from its top and bottom shielding. Make sure to remember which screws go where and note the keyboard connector orientation.

Step 2: Desolder all of the capacitors adjacent to the existing RAM chips. (DO NOT SKIP THIS STEP. You'll lose time if you do, and worse, the modification will not be reliable since you can't solder pins obstructed by the capacitors reliably (if at all)). To desolder them, I found it easiest to heat the island on the non-component side, and bend the wires straight. After

doing that on each capacitor, turn over to the component side and heat the islands while pulling the capacitor out with the tweezers.

Step 3: Open up the holes of all the desoldered capacitors, using a combination of de-soldering wick and suction tool. Do this from the non-component side. If certain holes are difficult to open up, you may want to use a wood splinter. (push it through while heating). Be carefull to remove all solder debris!! THE REASON for opening the holes NOW is that they will be less accessible once you've done the other steps! Patience is a virtue.

(NOTE: Step 2 & 3 are the only ones that may damage your ST PC board. Be sure not to use excessive force while pullling out the capacitors. If you damage your PC board anyway, cure the problem now and not later).

Step 4: In this step we will piggyback the new RAM's on top of the old ones. Be sure to connect all pins except pin 4 (RAS) and 15 (CAS). The best way to go about this is to do chip by chip. First, bend the pins of the new RAM's such that hey are perpendicular to the package (instead of having slightly spread "cowboy legs"). Use pliers to bend pin 4 and 15 suchthat it comes out of the I.C. package horizontal, and cut off the excess length of pins 4 and 15 (I mean part of the pin, you still need to be able to solder to it!). Make sure that the new RAM fits snugly on top of the old one (in the same orientation!!!), without intervening space and with the new pins touching the old ones. Now solder each pin (except the non-touching 4 and 15) to the other RAM's. The best way to do this with the least chance of damage is to touch both the new RAM's pin and the old RAM's pin. Heat them both for a second and add A LITTLE solder then. Wait till the solder flows. After each I.C., check all pins carefully to assure a good connection (use a magnifying glass). NOTE: This step is crucial for the long term reliability of the memory extension. A badly soldered joint may show up later as sporadic memory errors. TAKE YOUR TIME.

(NOTE: until step 6 is finished, do not in any way apply power to your ST. This intermediate state of affairs will damage your memory chips!!)

Step 5: Remount all the desoldered capacitors. Bend the pins like they were before resoldering, such that they will not touch the lower shielding. Solder from the non-component side.

Step 6: In this step you will route the 3 wires mentioned earlier. The first wire connects pin 4 (RAS) of all the new RAM's to pin 18 of U15. The second wire connects pin 15 (CAS) of the new U45 to U32 to 22 (CAS1H) of U15. The third wire connects pin 15 (CAS) of the new U30 to U16 to pin 21 of U15. The best way to do this is to use the stripper to remove 5 inches of insulation. Solder the first IC pin to the end of the blank wire, measure the distance to the next pin in sequence and shift over that amount of insulation. Continue in this fashion until all the pins in sequence are done. Work from U45 to the left, soldering directly to the leftover pins on the new chips. Make sure that no wire or solder sticks out above the the top plane of the new chips, since they will almost touch the top shielding! Route the wires through the PC board hole below and to the left of U15 to connect to U15 on the non component side.

Step 7: Sit back. Use Brain. Do you feel confident about the quality of your work? No mistakes? Check evrything once again if you are but a little uncertain. Applying power with errors might make your ST into a decorative, nonfunctional piece of art. OK. Either rebuild your ST into its shielding and cabinet, or put it onto a surface clear of wires and solder debris and connect it to monitor, disk and supply. Boot it.

It it boots, you're probably there. Test if the new memory works by looking at the phystop variable ($42E) with SID if you have the developer stuff. It should read $100000 (1M hex). Also note that memcntlr ($424) now holds 5 instead of 4, and that v_bas_ad ($44E) now holds $F80000 (screen bitmap origin). If you don't have the developer stuff, try a single drive copy and check that you get the whole disk in one buffer instead of two.

If the new memory does not seem to exist, use SID to deposit and retrieve words on locations $80000 and up (1/2 Meg hex). If bit errors occur, the ST bootROM did not detect the extension (it checks all bits of 512 locations by testing a psuedo random sequence, before accepting a memory bank). Try to pin point the faulty chip(s) and remove the error.

If it doesn't boot, you're in trouble. I'm sorry. It is difficult to give hints on what to do here. So many possibilities. Desoldering the new chips probably won't work (if the old ones were functional, the ST would still boot). Check for hidden shorts on the RAM pins. May also be that you have a flaky new pin connection.

That's all there is...

PLEASE REMEMBER THAT I HAVE NOT TRIED THIS AND I AM SIMPLY PASSING THIS ALONG FOR THOSE WHO WOULD LIKE TO TRY DOING THIS.

--Dwight McKay (75776,1521)

A forwarding note...

Well, there you have it. What I found in my ST was a revision H mother board. On this particular board are the provisions for two 68 ohm resistors that are installed in series with the CAS1H and CAS1L lines (R136, R137). There was also a spot where a connector could be installed that would route the 3 new control lines to the extra memory. Obviously, someone at Atari was thinking of a memory mod for this machine. Other than that, the instructions are correct. Believe the guy when he says to remove the by-pass caps first!!! If you have had any experience with a soldering iron or kit building, this project should present no problems.

Try calling Pacific Software Supply at 800-327-0425, I believe it is now $249.95. I'm not sure about version # though.

For me, it's a toss-up between this and TurboC - they both cost about the same. TurboC doesn't yet have English doc but has the potential to support C++ sooner or later.

Any more info on either would be appreciated!

Cheers

Joe

The internal bus (Megabus) is directly (parallel) connected with the CPU.
Only thing you have to do is to measure which pin leads to which pin of
the MC 68000. You have the pin assignment of the 68000?

785. Maxidisk- The best ramdisk there is

Newsgroup: comp.sys.atari.st.tech
Date: 1990-12-11 10:35:01 UTC
From: pv@polari.UUCP
Message-ID: <2875@polari.UUCP>
Source record: 49674

While people are proposing their favorite ram disks, I have to say something about Maxidisk.

Maxidisk will auto boot from an Auto folder. It will also start from the desktop. It's non-volitile. It will also auto copy disks, directories, or files contained in directories during boot up. Any size is selectable up to memory limits. Maxidisk is easy to configure
by editing a simple two line file with a text editor. Best of all, it COMPRESSES. Everything that goes in to Maxidisk is compressed 40 to 60%. When you look at the file sizes, the orriginal uncompressed sizes are shown. When you look at the total bytes, you become amazed when you see 550K worth of data in your 400K ram disk! OK...I will better one yet. It's PD!

I've not found any program that will not run from it. Since I don't have a hard drive, Maxidisk gives me the ability to do things on my one meg Atari that most people can't (like copying 800K floppies into ram with a 700K ram disk and still run programs). One little problem. The documentation is very poor and misleading. Requests sent to me for copies will get my little correction addendum. You might want to check this one out. You'll be very suprised.

Distributed a while back was a program to speed up GEM (not Quick ST, the other
one) in a demo version. It removed itself from memory after a certain amount
of use so its possible...

Sorry I can't remember the name of the demo program :-(

787. Question: Networks for ST computers

Newsgroup: comp.sys.atari.st.tech
Date: 1990-12-11 13:02:33 UTC
From: cb01@cs.vu.nl
Message-ID: <8476@star.cs.vu.nl>
Source record: 49687
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

G'day,

Can somebody please fill me in about the available networks
for atari ST computers? I've been working a while with a net
called ITOS but that _really_ doesn't work! A couple of days
ago I watched a demonstration of the BIO-net: this seems to
work great but is quite expensive (about fl.2600 (app. $1550)
per node) and because my net may grow > 10 ST's I'll need a
fa(s)t server. Summing up interfaces, ST's, drives and the
server I reach the fl.50000 (app. $30000) easily. This, I think,
isn't worth the bennefit of having bit-mapped-'intellegent'-
ST-terminals over character-terminals connected to some
bigger server (SPARC stations aren't that expensive!!).
I heard some rumours about ATARI launching their own net...
...
...
does anybody know anything about it? Is this a regular *ATARI*
anouncement (which means it will be available somewhere in
1994) or is it serious this time?

please, let me know if you heard *anything* (and I mean anything)
about some of this!!

greetings,

Joep Vesseur

The latter, I think... The Lattice C5 manual says something to the
effect that any memory belonging to a process which does a Ptermres is
removed from the free-memory pool, and is effectively lost forever
(or until the next reboot, whichever comes first).

A thought - can you stick the code above phystop, making it
reset-resident, and then move phystop back up again to 'delete' it?
Or do changes to phystop only get noticed on reboots? I might have
the wrong variable here, but do you all know what I mean?

Presumably the Mfree would not be able to re-insert the memory back
into the main 'pool'?

I am just starting to really get into the swing of working with my new St
and have seen some of the advanced options available for the ST and have
been impressed. What I would like to know is what is the best frame grabber/
video digitizer for the St. I have seen some of the work that Computer eyes
does and frankly I wasn't really all that impressed because it distorted colors
badly. However I am aware that there is some program put out by the same
compay that make computer eyes that apparently improves the color quality
drastically. Unfortunately I have not seen this in action. I am a amateur
turning pro video producer and would like something that digitizes the screen
from a VCR source so that I can alter the picture later. Thanks for any
help I get!
Thanks,

Thomas

Try checking out the mail order places, they are importing it for you, you register directly with Hisoft in Britain though. I got mine from Joppa Computers when at the Boston Atari fest this fall, I've now seen it advertised for less than I paid ($150) someplace else.

10 Mbps, $150 per node... LanTech Systems
uses coax with bayonett connectors rather like IBM3270 coax.
Allows sharig of hard-drives and printers and can be set up to
make a machine on the network look like it's the sole user of a shared
device. That's all I know... Hopefully someone can supply
LanTech's address or phone number....

>mentioned at all in the GCC docs).

I don't know a lot about atari GNU C, but if there is no accessory startup
code I can help. I have written startup code for Laser, Mark Williams,
Megamax, and Sozobon compilers that will start regular programs or desk
accessories. The code for all the compilers except Sozobon is owned by
Antic and was published in October 89 STart magazine. The sozobon startup
is public domain
and was posted to the Atari sources group; it is conceptually identical to
my own Laser C startup code.

I can mail it to anyone that is interested in porting it to the GNU
compiler. It is my hope that someday most accessories will be runable
as programs. (yes, I know about MultiDesk, a fine program that should
not be necessary)

794. Atari Mega ST bus notes

Newsgroup: comp.sys.atari.st.tech
Date: 1990-12-11 22:05:36 UTC
From: rdt154k@monu6.cc.monash.edu.au
Message-ID: <1990Dec11.220536.762@monu6.cc.monash.edu.au>
Source record: 49682

As there has been some discussion on the Mega ST internal bus of late
the following post briefly details the bus connections and what each
pins function is. Refer to any MC68000 data book for more info.
What is presented has been abreviated slightly but no
vital information was edited out. The whole document runs for about 10
pages, most of it esoteric, dealing with Atari's reasons for the bus and
copyright info plus a lengthy Introduction on the design of the bus. No real
information. Hope this is of help. If you have any queries please don't
hesitate to call me. Best of luck.

As to whether this is legal or not - I don't know. If problems do arise
as to the legality please inform me as I don't want to cause any serious
problems. Some parts are copied (ie; typed in by hand, by myself) verbatim
from the original documents.

---------------------------<cut here>---------------------------------------

Atari Mega ST internal bus.

Mechanical Description:

Two sizes of expansion card are supported. One, the half card
is half the depth of the Mega St unit. The other, the full
card is the full depth of the unit. In either case, the card
butts up to the rear panel of the St unit which has been provided with a
removeable hatch through which connectors and/or cables can be mounted.

The expansion card connects to the St motherboard through a 64
pin connector mounted on the bottom (solder) side of the expansion board.
This connector plugs directly into its mate mounted on the motherboard.
Standoffs, 25mm in length, are mounted into the bottom case through the
motherboard. the expansion card is then screwed down to the standoffs.
The standoffs and screws are not supplied with the Mega St and thus should
be included with the expansion card. A hole located in the left rear of
the expansion card fits around a plastic stud to provide extra strain
relief for rear mounting connectors (See diagrams).

Electrical Description:

The signals provided on the 64 pin connector are essentially the
pins of the 68000 processor. These signals are all unbuffered. They are
intended to drive one LS TTL load on the expansion board. driving more than
one load or driving excessive capacitance may cause imporper St operation.
For this reason it is not acceptable to connect to the expansion connector
in any manner other than the one outlined in the previous section (e.g.
connecting directly with a cable is not acceptable.

The bus may be arbitrated away from the processor using the normal 68000 protocol. However, the bus grant signal provided on the connector is the end of the daisy chain. Response time will be effected by the DMA going on in the system (e.g. disk activity, hardware bit-blt transfers, etc). If the peripheral requires DMA to occur while interrupts are enabled, care must be taken to limit the transfers to bursts of less than about 50 bus cycles allowing adequate time between bursts to process the interupts.

The timing of the bus is that of any 8Mhz 68k processor. Since the signals provided are essentially the processor pins, connecting peripherals in the same manner as you would to any 8Mhz 68k should work with no problem. DMA is the exception. The bus cycle produced even while the bus is arbitrated away from the processor must look exactly like an 8Mhz 68k bus cycle. This constraint is necessary to provide the proper sharing of the memory between the processor and the video. In all transfers, DTACK must be provided/sampled as required by the 68k processor specification. Also, transfers may not last more than 64 clock cycles. The St will automatically generate a bus error if AS is held low for more than 64 clock cycles.

The following diagram shows a top view of the connector on the motherboard with its associated pin numbers and signal names. This connector (TRW no. 009-00002-8, JAE no. ME03-R64P-D4T2-A1 or equivalent) is the male side. The expansion board uses the female side (TRW no. 009-00005-6, JAE no. ME03-64S-D4R1-A1 or equivalent).

<front of ST rear of ST>

Top view of motherboard connector.

The following is a brief description of each signal on the connector.
For more detailed info consult a 68000 processor manual.

CLK

This signal is an 8.0106Mhz TTL compatible, 50% duty cycle square wave.

/RESET, /HALT

In combination these two signals can be used to indicate a system
reset. The /RESET can be used by itself to indicate a system or s/w
reset (RESET instruction executed). These are both bidirectional
(open collector) signal terminated on the motherboard with a 1K and
a 4K7 pullup respectively. They may be driven according to standard
68000 processor timing to acheive the functions of the 68000's
/RESET and /HALT lines.

A system reset will occur at powerup and any time the reset switch
is pressed. It causes both lines to go low for at least 1ms. A
software reset will cause only the /RESET line to go low for
approximately 15us.

A1-A23

These lines provide the 23-bit address directly from the 68000
processor. Terminated with 4K7 pullups on the motherboard.

D0-D15

16 bit bidirectional data bus. Terminated with 10K pullups on the
motherboard.

FC0, FC1, FC2

These lines indicate the processor status for the current bus cycle.
They are directly driven by the 68000 processor. Terminated by 10K
pullups on the motherboard.

/AS

When low, indicates valid address on address bus. Terminated with
4K7 pullups on motherboard.

R//W

When high, processor is doing a read. When low, processor is doing
A write. Terminated with 4K7 pullups on motherboard.

/UDS, /LDS

/UDS indicates upper 8 bits, ie; D8-D15. /LDS indicates lower 8 bits,
ie; D0-D7. Terminated with 4K7 pullups on motherboard.

/DTACK

Bidirectional signal used to indicate a completed data transfer.
Terminated on motherboard with a 1K pullup

/BERR

Used to tell the processor or DMA device that no peripheral device
has reponded to the current bus cycle. The ST will automatically
generate this signal if a bus cycle does not complete within 64 clock
cycles. Terminated on motherboard with 4K7 pullup.

E

Enable clock used for 6800 peripherals. 60/40 duty cycle.

/VPA

Open collector line used to indicate that a 6800 type cycle should
be executed. Terminated by 4K7 pullup.

/VMA

This signal is used to synchronise 6800 type bus transfers with the
E clock.

/BR

Indicates that the bus will be released at the end of the current
bus cycle. This signal is daisy chained through the other DMA
devices on the motherboard, it does not come directly from the
processor.

/BGACK

Open collector signal used by a DMA device to claim bus mastership.
Terminated by 4K7 pullup on motherboard. Should also be terminated
on expansion board with another 4K7 pullup.

/NMI, /INT-5, /INT-3

These signals are used to asynchronously generate a level 7, level 5
or level 3 interrupt. These are the only levels which can be generated
externally. If they all occur simultaneously, the highest priority
(level 7) will be acknowledged first. The expansion card is responsible
for responding to any interrupt acknowledges for interrupts which it
generates. These acknowledges can be either vectored or auto-vectored.
All three lines are terminated by a 1K pullup on the motherboard.

Power:

Power is supplied to the expansion card through a pigtail cable which plugs onto a six pin connector on the motherboard. The connector on the mother-board is AMP no. 171825-6. The mating connector on the pigtail from the expansion borad is AMP no. 171822-6. The drive capabilities are as follows;

PIN 1 - +5VDC @ 750mA
PIN 2 - +5VDC
PIN 3 - GND
PIN 4 - GND
PIN 5 - GND
PIN 6 - +12VDC @ 500mA

Software Considerations:

The mediation of available addresses should not be necessary since only one expansion card may be plugged in at any one time. Atari has set aside the addresses C00000 through CFFFFF, FF0000 through FF7FFF and FFFE00 through FFFFFD for use by outside developers. Spurious accesses to FFFFFE/FFFFFF may be generated.

You can't add RAM which will work as video memory and/or will allow DMA. Also if memory is extended on the expansion card, the operating system will not clear it or allow it to be allocated.

Computer Eyes I think is the best, or at least, the most popular.
(We all know that most popular doesn't mean the best. :^) It only
digitizes in 16 colors, but read on....

- However I am aware that there is some program put out by the same
- compay that make computer eyes that apparently improves the color
- quality drastically. Unfortunately I have not seen this in action.

There is a desk accessory called DIGISPEC which allows you to use
Computer Eyes and digitize 512 colors on the screen at once. This is
written by a company called Trio Engineering which also wrote
Spectrum 512, the 512-color drawing program which preceded DIGISPEC
and Unispec, a 512-color animation program. I have seen results of
the Computer Eyes and DIGISPEC combination, but have never seen it
being done. Antic used to distribute the programs, but I'm not sure
if they still do. You can find them via mail order or if you have a
good local dealer.

- I am a amateur turning pro video producer and would like something
- that digitizes the screen from a VCR source so that I can alter the
- picture later. Thanks for any help I get!

DIGISPEC will allow you to change brightness, contrast, hue
saturation and a couple of other things, like convert GIF pictures to
SPC (Spectrum Compressed) format. Spectrum 512 will allow you to
manipulate the images, like cut and paste, add colors, gradient
fills, etc.

Hope this helps.

I have a friend who was wanting to upgrade his SS external Atari ST disk drive to DS. He bought a new DS mech. at a local computer shop and hooked it up in place of the SS mech. in his drive, but it would only work very intermittantly. So, he went back and got a different make of DS mech. and tried it with the same results. Does Atari use special mechanisms? These mechs. that he tried, had the exact same connectors on them as his old unit. We figured that even if the SS drive's electronics couldn't support DS operation, that at least these mechanisms would work in SS mode... He was able to get a directory a coupla times, but very slow.. Never able to format or write.... ..He was successfully able to look at text file... The were IBM type 720K mechs. that he was trying to use... ..Anybody know if this kinda upgrad is possible? ......Yonderboy@cup.portal.com

797. Redirect stdout to a window

Newsgroup: comp.sys.atari.st.tech
Date: 1990-12-12 08:08:35 UTC
From: klute@tommy.informatik.uni-dortmund.de
Message-ID: <2852@laura.UUCP>
Source record: 49685

Now that Arcgsh 3.5 is out it is time to think about new features to be integrated. Something I really would like is to redirect standard output so that it goes no longer to the screen but to a GEM window.

I would like to catch the character output to the screen, handle it my own way and display it in a window. This would offer some fine options:

The output would not be lost when scrolled away. You could browse through the whole output - of course depending on the available memory.

The output could be edited and saved to a file.

You could "cut" certain portions of the text and "paste" them elsewhere. For example create a Zoo archive listing with "zoo l foo.zoo", then select one or more element names and extract the selected elements from the archive.

Now my question: I am sure someone has done something like that already (at least the screen output catching as such) so that I would not have to re-invent that particular wheel. A set of routines in C or assembler would be fine.

Thanks in advance!

>
> I need something much more precise than that. Any idea?

No, there is no more precise date/timer which return
hour,minutes,seconds.
But you can the 200Hz Timer (=5ms) to measure small
durations. There is a long value at address 1210 which
is being incremented 200 times per second since system boot.
(counting 5ms ticks). You must be in super mode to read
this value.

Maybe this will help you

From: kentd@FtCollins.NCR.com
Message-ID: <KENTD.90Dec12092926@zappa.FtCollins.NCR.com>
Source record: 49688

There was a discussion here about SPICE a little while back. It seemed
that everyone wanted it and a few people knew of a port of it.
What was the conclusion? Was it ever made available? Will it?

If not, does anyone want to help me get the source code and so I can
start working on the port? (any help gladly accepted :^) I can't ftp
and Berkeley wants $200 for 8 disks worth of source code. Supposedly,
they only charge material and handling fees, but with bulk disks well
under a dollar they must 'handle' the heck out of 'em! :^}

I'd be more than happy to sign their non-disclosure agreement.

Lantech Systems
PO Box R
Billerica, MA 01821
(508) 667-9191

My church has been using Lantech for about 5 months to network 2 Mega 2s together. At first each Mega had a hard drive, but since the net has been working so well we took one of the drives off. Now we have a Mega 2 with a 85meg Toadfile as the host and a Mega 2 as a stand alone in another office. Lantech also includes a neat little desk accessory that allows you to use any printer on any node on the net. Works great for sending messages ;-) and there is also an e-mail utility.

I am not connected with Lantech. I am just a happy customer.

Could anyone please supply an objective reveiw of Lattice C V5 and of
Prospero C. Reason being, I would like to port some ANSI compatible C
code over to the ST. Which of the two is the better value for money and
which is easier to use and how close does each adhere to the ANSI C standard.
Also I would like to know, could they handle K&R code without too many
problems. Thanks in advance.

>Computer Eyes I think is the best, or at least, the most popular.
>(We all know that most popular doesn't mean the best. :^) It only
>digitizes in 16 colors, but read on....

I have color computer eyes.

First I would like to say that the company that makes color computer
eyes is one of the best I have EVER had to deal with. They have MY
highest recommendations.

Color computer eyes scans a signal and produces RGB data.
The ST low res normally supports 16 colors-- thus the normal
image shown with color computer eyes has 16 colors.

Now, you can do anything you want with the RGB data and one program
out will use this data to make a Spectrum picture. With this addition,
I find the images quite acceptable.

The resolution for these images is 320 pixels by 200 pixels.
When these images are viewed on a Sun, for example, with its
1152x900 pixel screen-- the image looks rather small.

There are various ways to provide a signal for color computer eyes: I
tend to use a digital vcr with STOP frame. Even without a tape in the
mechanism, I can press a button and freeze the image on the screen.
This image is perfectly still. I find that the scanned image will be
almost identical (sometimes the TVs color settings are slightly off.)

Next, I have used a color camera (I don't have details), but I find
that the LIGHT used makes a world of a difference. I find that the
best images are scanned DIRECTLY from the camera with a BLUE light.
These images are quite sharp and they are exactly what I was looking
for when I purchased the video digitizer.

Send me email if you want to talk more...

From: heavy@zip.eecs.umich.edu
Message-ID: <1990Dec13.010645.26481@zip.eecs.umich.edu>
Source record: 49695

I am trying to write a shell, and I have a few questions...

1. Not totally to do with a shell, but when you double click on
a program to run it from the desktop, it puts the name in the
center of the menubar while it is loading it, how do you get rid
of this if you are not using a menubar?
2. What is the preferred way to run a program from inside another
program (Pexec/shel_write) ?
3. How do you clean up after a program exits (they leave their
garbage on the screen) ?

Thanks again...

I've recently written a small screen dump tool for my NEC P6+ on my MEGA ST,
which has the blitter TOS (TOS 1.2), using scr_dump ($502). I tested it on a
TOS1.4-machine and it was running.

So all at all I can say:
The screen dump vector didn't changed (Maybe in TOS 1.6, but I don't think so).

> upgrad is possible? ......Yonderboy@cup.portal.com

As long as they have a 3 ms stepping rate, also does your SS drive box have a small PC board with a large I.C fitted, this is better removed also you will find that the side select line is not conected, so it depends on the version of rear connector card, if it has the large ic. it is a bit of a pain, but posible, i did have one SS drive that had 2 small ic's on the rear board, but they were to buffer the Step/Write data lines, NOTE: don't use 1.44 meg drives, they won't work, i have 2 NEC FD1037A drives and they work perfectly, but have had some seek problems with Mitsubishi MF353B-12U drives, they are quoted as being 3 ms, but the agent here states that they test them as 4 ms, but if you can get a true 2/3 ms Mitsubishi they are very good drives, also note some drives the Pin connector is the othere way around...

>[good stuff about how Maxidisk compresses, autocopies, etc.]

Does Maxidisk handle files bigger than 512K? I don't know why, but most
of the RAMdisks I've tried seem unable to handle big files. To test
any given RAMdisk, I copy nethack.ttp (> 600K) into the RAMdisk, and
then try to run it. With almost all RAMdisk drivers I've found you
get two bombs when you try to run the copy. :-(

Edisk is a notable exception to this rule. Does anyone know why
big files cause problems with most RAMdisks?

813. Big logical sectors and their effects

Newsgroup: comp.sys.atari.st.tech
Date: 1990-12-13 14:12:10 UTC
From: dmb@wam.umd.edu
Message-ID: <1990Dec13.141210.26853@wam.umd.edu>
Source record: 49698

I was looking over my ICD host adapter docs last night, and found that you can set the "logical sector size" as big as 8K. The implication was that you could have really huge partitions (e.g,, 512K per _partition_) this way.

What effect does changing the logical sector size have on the system? Does it increase minimal file size? E.g., if I create a 10 byte file, will it take up 8K on the disk, since the sector is the smallest unit of space that can be allocated?

Will a large sector size decrease performance? Confuse applications of any kind?

Hi there!

I wonder if anyone knows what modifications are needed to replace the 8 MHz 68000 processor in the Atari with a 16 Mhz one. I've seen a mod in an English ST Magazine for about 199 pounds (approx. $400), which I consider a bit expensive! Has anyone actually tried to do this, or does anyone know the necessary changes (e.g. interfacing to the MMU, GLUE et al).

Please answer by email. If there is enough interest, I'll summarize it to the net.

>Dave Baggett
>dmb%wam.umd.edu@uunet.uu.net

Hmmm. If you have a 1040, isn't 1040/2 = 520 ? I always thought that if you have a ramdisk, the program still has to be "loaded" into the memory. It's just that it is so much quicker to copy memory->memory, it's not noticeable.
So unless I'm totally off on this one, you won't be able to run files bigger than 512K unless you get a memory upgrade...:-(

Having recently purchased a mono monitor I have a question. Has anyone thought of a way to have the ST use it with everything in the same proportion as in color? (the 8x8 font for everything, including the menu bar, etc) For example, when you call up a directory, the window has twice as many names listed since they are the smaller font, sorta like 49 line mode.

It looks like the mouse pointer does it, and so do the icons. (They don't have the stretched out look like they do in medium rez.)

Does this make sense? (Its awfully hard to explain.)

| Hmmm. If you have a 1040, isn't 1040/2 = 520 ? I always thought that if
| you have a ramdisk, the program still has to be "loaded" into the memory.
| It's just that it is so much quicker to copy memory->memory, it's not
| noticeable.
| So unless I'm totally off on this one, you won't be able to run files
| bigger than 512K unless you get a memory upgrade...:-(

This is wrong! It depends on *how* the file is copied to the RAM disk. On my old 1040 ST I've had RAM disks as large as 700 Kb. Never had trouble with huge files. Only if gulam had less than 60 Kb available to do the copying.

Cheers,

From: Yonderboy@cup.portal.com
Message-ID: <36917@cup.portal.com>
Source record: 49709

I started this thread by meantioning how my friend was having trouble upgrading his SS external drive to DS.. He tried two 720K Mechs and they both failed! He went out and bought a 1.44M mech and tried it and it worked! Go figure?!?! Anyways, I guess it can be done. He simply hooked the thing up and it worked. I did receive mail telling me that there are 2 types of external drives... One has normal IBM style drives in them and another type uses some cheaper mechs. that need support circuitry (found in the case of the Atari drive) to drive them. It was reported that these (the latter) type of drive is harder to upgrade... Well, good-luck to anyone else who wants to try this... It looks kinda hit-or-miss.. Note, this message seems to contradict the message concerning 1.44M drives NOT working.. who knows, eh?

822. Expanding Megafile 60 (summary)

Newsgroup: comp.sys.atari.st.tech
Date: 1990-12-14 15:56:37 UTC
From: swklassen@rose.uwaterloo.ca
Message-ID: <1990Dec14.155637.8235@watdragon.waterloo.edu>
Source record: 49711

Here is a summary of the info I got regarding adding another drive
to my Megafile 60.

Some have stated that it is possible to add another drive to
my current controller, it looks like it is not the sort of thing
that I would want to do. I was hoping that it would be just a
matter of opening the case, mounting the drive and plugging in
the cable (and possibly setting a dipswitch or two). Instead
it seems that it is more complex for a number of reasons:

1) It seems the cable for the second drive has been cut off of
the controller, hence a new one would have to be installed.

2) One person mentioned that the Adaptec controller has been
modified so that data can not be read from a second drive (some
lines have been attached to ground) and these modifications
would need to be undone.

3) A new power supply might be needed.

4) I would have to write my own software as HDX will not support
the second drive.

My question for Atari is: Why has this approach been taken? I would
think that the ability to just "plug in" a second drive would be
a useful marketing tool. Instead it looks like you have gone to
extra expense to ensure that this cannot be done.

My reaction is: Too much work/risk for me to undertake. I guess
I could purchase a second Megafile but perhaps I should just save
my money to buy a better machine.

From: <>
Message-ID: <1990Dec14.183620.13254@cs.utk.edu>
Source record: 49713

In the GEM application I'm writing, I'd like to be able to put a bitmap/logo in the middle of the screen (i.e. like TURTLE or ARCGSH do). I constructed one using the Resource Construction Program, and can display it ok (as an object). But, when I invoke a desk acc. that opens a window (i.e. Control Panel), and then close it, I get no message from evnt_multi that the screen has to be redrawn, and the accessory with the window does not update the stuff under it (so that my logo disappears!).

I tried opening a 'dummy' window for the whole screen to get on the window update list, but although now I get the update message, weird things happen on the screen.

There just has to be a correct way of doing this (making sure that my logo is always updated when necessary). If anybody knows about this, I would be in your debt forever if you let me in on the secret.

Please send e-mail to andrew@cs.utk.edu.
Thanks,

-andrew krzywdzinski

Gnu C is free and ANSI-compliant (fully), and it also works _very_ well
with K&R code (use the -traditional flag). It needs at least a 2 meg
machine, though. With MiNT and the MiNT library, you can port Unix code
practically unmodified (just change a file name here and there, ie.
.emacsrc > emacs.rc).

826. Enlarging the address space

Newsgroup: comp.sys.atari.st.tech
Date: 1990-12-14 22:08:44 UTC
From: adamd@rhi.hi.is
Message-ID: <2542@krafla.rhi.hi.is>
Source record: 49716

I am enlarging the address space on a 1040 ST, in order to add extra ROM etc.
By the looks of it, the /DTACK signal needs to be asserted when an address read
access is made to the new ROM area. Does anyone know what kind of output drive
capability is necessary on the logic which outputs /DTACK ?
Also (for another reason) I would also like to generate /BERR.
Does that need the same output drive as for /DTACK ?
I'm asking because there seems to be no spec sheet available for the ST custom
chips.

Thanks in advance.

The minimum file size would be 16k. The allocation unit is 1 CLUSTER not 1 sector. A cluster is equal to 2 sectors (normaly)

>Confuse applications of any kind?
Some disk analyzer and defragmentation programs like DLII will not work properly. I assume Ataris new disk analyzer will work with the larger sectors, since there latest formater uses them.

I posted a follow up to your original, stating that I had a similiar problem
with my Mega clock loosing time.

>| What's the accuracy of the real-time clocks that come with Mega STs?
I don't know, but when I opened up my Mega this weekend I found that there is
an adjustment for the clock 'speed'. It is small potentiometer right near the
clock chip. I turned it clockwise a 1/16 of a turn. I don't know yet what
affect, if any, it had on it.

>Even rebooting causes an additional loss of a couple of seconds.
Woa, are you sure you don't have a time setting program in your auto folder,
or a time setting desk accessory? If you do then that is most likly what is
causing your problem (based on this re-boot comment).

>Anything I can do to get more accuracy?
Adjust the pot as above.

You forget that this is Atari you're talking about. They don't market hard drives, or STs for that matter. (Actually, a friend of mine, the one that tells me about the $400 386 systems, saw an Atari ST co-op ad one morning during the Today show. Had the dealer's address and phone number at the end.)

- My reaction is: Too much work/risk for me to undertake. I guess I
- could purchase a second Megafile but perhaps I should just save my
- money to buy a better machine.

Or a better hard drive. I would think that people who read this net would know better.

I recommended an ICD drive to a friend of mine who knows nothing about hard drives, and he went out and bought a Megafile 30 for $500. He could have had a larger drive and better host adapter and software for that price if he would have heeded my recommendation. It boggles my mind when I recommend things to people after they ask me, and they go ahead and do the opposite.

That's because the AES decided your window covered the whole screen,
and therefore your redraw would take care of everything, and it didn't
have to update anything. The right way is to open a window just
the size and location of the logo. Then that window will get redraw
messages when parts of it are exposed, and the Desktop background
will get redraw messages for the rest of the screen.

There is a system variable that holds the time since the system was
booted, in 1/200ths of a second. For measuring time spans, this works,
but you still can't get real time-of-day any more precisely than two
seconds.

>6. Call form_do( ) to let the AES handle the dialog.
>7. When you get control back again, call form_dial(FMD_SHRINK, ...)
>8. Call form_dial(FMD_FINISH, ...) to free up screen space

this is the "normal" way of doing it, but it does have limitations. i think the max dialog size is 1/4 the screen as that is all the memory form_dial deals with. i may be wrong here, though...

there is a better way, at least i use it:

1) as above
2) save ALL the screen to a 32000 byte buffer
3) objc_draw anywhere u like
4) form_do as above, in a loop while (!exit_condition)
5) on exit, restore the entire screen from the buffer

you don't get the (silly?) growbox/shrink box (my beta testers told me to ax them on some code i produced a while back).

this allows you to draw dialogs as big as the screen. the screen save/redraw is virtually instantaneous. users have the need for speed. u can also draw the dialog anywhere (on the screen makes most sense, though i think it is possible to draw it off screen and clip to the screen - i actually think i needed to do this once, but don't quote me).

u get the screen location from Physbase or Logbase calls (forget which). i think vro_cpyfm is what i use to copy the screen, though tight loop copying longs should work, too. jeez, it's been a while...

i wrote a gettimeofday(2) call which did the Gettime/Getdate, but also gets the current value of the 200 Hz timer (just a system variable, long at 0x4bc, access in Super mode). that gets u down to 5 ms which i then use to get the second and stuff the rest in the tv_usec field of the struct timeval (sys/time.h).

if u can't figure it out, i can send it to you...

ATSpeed, which is out now, emulates EGA and VGA monochrome.
Of course, if the software makes hardware calls directly to
the video adapter, then the emulator will probably not be able
to handle it (then again, this will probably be hard for any
emulator). The idea of having an actual VGA card along with
an emulator (a la the proposed card for SuperCharger) might be
the way you have to do it.
In any event, I've got ATSpeed now and I really like it. It
can handle Windows (I don't have 3.0, yet), and it even runs a
piece of software that involves different fonts and keyboard
remappings...the key is being able to load different fonts,
and this is accomplished by a dos program provided with the
emulator itself.

841. Memory upgrade woes

Newsgroup: comp.sys.atari.st.tech
Date: 1990-12-16 10:28:42 UTC
From: system@n6vbg.hamavnet.com
Message-ID: <1990Dec16.102842.66@n6vbg.hamavnet.com>
Source record: 49731
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

Hello everyone,

I'm thinking about adding some more memory to my 1040ST, and I was wondering if those of you who have done so in the past would share their experiences here. Is there any recommendations as to what products are reliable and which ones are not (i.e., Zram, JRI, etc).

Thanks,

842. Memory deallocation after TSR

Newsgroup: comp.sys.atari.st.tech
Date: 1990-12-16 14:30:16 UTC
From: 72347.2767@CompuServe.COM
Message-ID: <"901216143015.72347.2767.EHA33-1"@CompuServe.COM>
Source record: 49732

One technique is to load no go (seems to work as documented after TOS 1.4). I use this technique to load RSXs into my CLI. They stay in memory until I ask them to leave. Each RSX registers with a resident manager that keeps up with the address of a clean-up routine to call before kicking the program loose. The clean-up routine should Mfree() any Malloc()ed memory the RSX requested. It should also keep track of Files the RSX openned on its own and and other variables that must be reset. One RSX I have is an installable/uninstallable printer spooler. Others add to the CLI built-in command set.

Once cleanup is called the resident manager Mfree()s the basepage and the prog's environment space. I've been using this technique very successfully for a few years without problems--except you should be careful about uninstalling RSXs out of order since Malloc and Mfree lose efficiency then.

BTW RSX==Resident System eXtension (an old CPM acronym).

Robert Royar

Cratylus Educational Software

One thing I forgot in rushing to respond to the thread about deallocating TSRs was that the RSX scheme I described does not depend on Ptermres(). In fact if the RSX were to call either of the Pterm()s or Ptermres(), disaster would ensue. TOS believes the RSX's parent is the owner of all resources the RSXs control, and the RSXs run as subroutines of the parent, not as separate processes. I don't use "just go" to start an RSX, rather when the RSX loads, the resident manager computes the starting-instruction address from the basepage returned by the Pexec() load, no-go call. That starting address is an init routine that sets up the RSX internally and registers its "official" entry and clean-up routines with the resident manager. For spoolers the init routine is just a dummy, but for CLI extensions, the entry routine dispatches that RSX's working code.

As an added benefit to the RSX and to keep RSX size small, the resident manager installs pointers to some re-entrant routines in an RSX jump table. In the RSX a function can call strcmp(str1,str2) normally, but the internal routine is
_strcmp: jmp _strcmp
The jump is patched up by the resident manager so the call goes into a routine in the CLI's shared library. This added stuff is not required to make an RSX scheme work, and would break in an environment where routine's addresses may change after load, but for most uses on an ST, the jump table is a real win. Just being able to write a program that calls all the standard C string functions and the formatted print functions without their having to be linked into the executable saves quite a bit in file space, executable space, and load time.

Robert Royar

843. Enlarging address space

Newsgroup: comp.sys.atari.st.tech
Date: 1990-12-16 17:27:29 UTC
From: adamd@rhi.hi.is
Message-ID: <2547@krafla.rhi.hi.is>
Source record: 49733

What I really meant was:

Is it sufficient to put a diode on a TTL output in order to pull /DTACK low
on newly-defined address regions (wire-AND)? Is this enough to stop GLUE from
generating /BERR on normally non-existent addresses? What is the upper limit
for the number of such /DTACK ANDed inputs to guarantee correct operation?
I see no reason why it shouldn't work for small numbers unless GLUE is actively
banning larger addressing ranges.

Have any spec. sheets been made available for the custom Atari chips or do we
still have to guess and make mistakes, not knowing whether an experimental
circuit works by accident or by design?

Is there a list somewhere of which 3rd-party products use which extra addresses?

Thanks in advance for sensible info.

Source record: 49735

Why not STE? Because of STE has its 68000 on PLCC-socket and other STs
have it on DIL/DIP package.
An adapter for STE is only a question of time, maybe someone can make one
himself, I would give a try. And Vortex has an adapter to connect ATonce
to STE, that should work with other expansions as well.

What are you saying? I fits to Megas as well, no difference!!!
It can not even be considered to be mounted to the megabus because
you should remove the old 68000 anyway. ST cannot tolerate two 68000s!

847. Dialog Box Woes

Newsgroup: comp.sys.atari.st.tech
Date: 1990-12-17 05:53:51 UTC
From: schultzd@kira.uucp
Message-ID: <1990Dec17.055351.8596@msuinfo.cl.msu.edu>
Source record: 49737

I get three bombs in a dialog box prog that I wrote. I narrowed it down to one of two things, but I don't have the documentation on the function calls used.

Problem Choice #1:
Incorrect use of the rsrc_load() function. Tim Oren's "Professional GEM" says use...

```
ok = rsrc_load(ADDR("blahblah.rsc"));
```

(When I compile under sozobon with GEMFAST lib, I get _ADDR is undefined.)
Instead, I use ...

```
ok = rsrc_load("blahblah.rsc"); /*This compiles*/
```

Problem Choice #2:
Incorrect parameters to form_do(). What exactly is this function expecting? Is there a limit to the size of box form_do() can handle? (Someone mentioned 25% of the screen. I need a bigger box.)

Anyway, hope thats enough. Please help me out on this one!

```

> 3) objc_draw anywhere u like
> 4) form_do as above, in a loop while (!exit_condition)
> 5) on exit, restore the entire screen from the buffer

AAAARRRRGGGGGLLLLL !!!! Never do that !!!! NOW, the screen buffer is
32000 bytes long, but if you uses a greater scrn, your routine will only save a
small part of it... Same thing if you use Protos or any other screen soft-
enhancer...

THIS IS DEFINITELY NOT A GOOD WAY OF PROGRAMMING GRAPHICS !

With such hints, when the resolution or the hardware changes, the
program does not work any more ! A good development muST work on all ST-models
with any hardware you want... I know this not easy to realize, but it's the
price you have to pay if you want to see the ST as a professional computer !

Daniel.

>Does it increase minimal file size? E.g., if I create a 10 byte file,
>will it take up 8K on the disk, since the sector is the smallest
>unit of space that can be allocated?

When boosting the sector size up to 8 KB, the minimal file size is
16 KB when using 2 sectors per cluster (standard case), and a _cluster_
is the smallest unit of space to be allocated.

>Will a large sector size decrease performance? Confuse applications
>of any kind?

Large sectors probably won't hurt performance. I haven't done any exact
measurements on that one yet. Many disk editors don't know about big
logical sectors yet but are being adapted. Application software
doesn't need to know about things like this and therefore runs
unaffected.

From: moses@hao.ucar.edu
Message-ID: <9576@ncar.ucar.edu>
Source record: 49740

Does any one know of the location of a resource converter utility
that will convert from the KUMA resource editor format to the WERCS
format (visa-versa)? Besides the *.RSC and *.H files produced there
is the *.RSD file that is used by the resource editor internally.
Loading a WERCS file into the KUMA editor, one loses all OBJECT name
information and some other things too.

The WERCS resource editor is the better of the two but KUMAS has some
features that are unique to it.

good point, though i plead pressed for time :-)

actually, if u look at all the examples of "good" programming atari put out "in the beginning", this was often used. the "correct" way is to first ascertain the size of the screen (one of the open workstation workout[] entries, as i recall) then malloc/Malloc the space. maybe i SHOULD have said "allocate enuf space for the screen and save it to this buffer" rather than 32k. picky, picky...

> THIS IS DEFINITELY NOT A GOOD WAY OF PROGRAMMING GRAPHICS !

aw, c'mon, dan. it is not THAT bad. lighten up!

and it is the only way i know of to use dialogs larger than 25% of the screen. unless u can suggest a better approach? i'd gladly change my evil ways :-).

> With such hints, when the resolution or the hardware changes, the

i really do not think this affects most *current* ST owners. and i use line A, too, so u can get on my case there, too, since i don't think the TT supports it, though this has been a sanctioned as OK by atari up to now, i believe (since i got a nice laser-printed S.A.L.A.D. from atari maybe 1.5 yr ago).

i don't know what u mean by "automatically" vs "manually". you can install a new mouse position vector with vex_motn (i don't remember the exact name but this is at least close). it is called with mouse x,y in d0/d1 and you can change it. before your handler does its rts, it can change the d0/d1 based on some application-specific action, and the new coords get passed on to the AES. from that point on, the AES updates its idea of where the mouse is based on your d0.w/d1.w values. i don't know if this can be done in C. it will be non-portable at best (using asm(...) statements).
i wrote my handler in assembler and have had no problems.

>Will doing this cause any problems with the AES? Make it lose track
>of the mouse?

there should be no problems. just make sure to restore the old handler before your application finishes...

Hard drives are usually set to dma address 0. You will have to open up one of your drives and change its dma address to 1 by changing DIP switches or moving jumpers. If you make your friend's drive unit 1, then his CDE... partitions will come up after your partitions, as HIJ... . Be warned that opening the case may void your warranty!!!

What he said.

There is another side-effect to large sectors, however: your disk cache must consist of sector buffers which are as big as the largest logical sector in your system. Our hard-disk driver and cache program handle that case perfectly: the cache program (CACHENNN.PRG) interrogates the driver, asking "what's the largest logical sector size in the system?" and it sizes cache sectors accordingly. Other cache programs probably do not handle this: they probably assume 512 bytes per sector.

As for clusters, clusters are always 2 sectors long. This is due to a bug in GEMDOS. (The bug is interesting: it says, in effect, "if this isn't the first sector of the cluster, then it's the last." Hence, two sectors per cluster.) It's possible to fix the bug, of course, but a disk with clusters larger than two sectors could not be used on a system with older ROMs, and since large logical sectors fix the same problem in a way that doesn't rely on having new ROMs, we decided to do it that way.

>What are you saying? I fits to Megas as well, no difference!!!

Aha, what I was actually saying:
Maybe there's not enough room in a non-Mega for _lotsa_ extra hardware.
I have a 1040 with two internal drives, internal Spectre GCR, ST-QL shifter
board, 16Mhz Hypercache. All that without removing the shielding. I'm not
sure there's going to be enough room in there for a board with 386, '030 and
their two FPUs. On the other hand I've been considering replacing the PSU with
a slimline hard disk (both the same size), and using an external PSU.
Old style disk-drive connectors cannot be unplugged by accident, unlike the
standard ST power cord. It seems also to make better sense to have DC power
backup than using mains voltage AC inverters just to get back to old DC.

>you should remove the old 68000 anyway. ST cannot tolerate two 68000s!

Well, it would be nice to try, if that was the excuse needed in order to ditch
TOS for good :-) What about one for I/O and one for CPU work.

You can certainly save everything on the screen without knowing that
it's 32k bytes long. Try finding out how big it is and then blit it
into a buffer and back.

>"Professional GEM" says use...
> ok = rsrc_load(ADDR("blahblah.rsc"));
> (When I compile under sozobon with GEMFAST lib, I get _ADDR is
>undefined.)
> Instead, I use ...
> ok = rsrc_load("blahblah.rsc"); /*This compiles*/

ADDR() is one of the "portability macros" that allows you to write GEM source that will compile both on the ST and for IBM PC GEM. Few if any people use them anymore. This is mentioned at the end of Pro GEM IV, and in part XVI he stops using them.

I think the basic rule is that you can always pretty much delete them.

>Problem Choice #2:
> Incorrect parameters to form_do(). What exactly is this
>function expecting?

form_do() expects the address of the tree and an integer # of the first text field. You can get the address of the tree by using rsrc_gaddr() or by a hack. Let's see, this is how my program TeXShell loads and displays the menu bar, which was called MYMENU in the RCS:

```
#ifdef RCS
rsrc_load( "texshell.rsc" );
rsrc_gaddr( 0, MYMENU, &menu_adrs );
#else
fix_objects();
menu_adrs = rs_trindex[ MYMENU ];
#endif

menu_bar( menu_adrs, 1 );
```

The first version reads in a .rsc file and uses the function call to get the address. The root of the tree in this case is object 0.

The second version uses the fact that my resource-to-C conversion program sticks the addresses of the object trees into an OBJECT * array called rs_trindex. This is a little more obvious if you look at the output of the conversion program.

> Is there a limit to the size of box form_do() can
>handle? (Someone mentioned 25% of the screen. I need a bigger box.)

I don't know, but if you start small you should be able to get it to work without bombs. When GEM gets confused, bombs away.

>evil ways :-).

There is no limit to the size of a dialog. A dialog can fill the entire screen.
This is because the area covered by the dialog is not saved in bitmap form,
but instead is redrawn by GEM and the application that owns the window(s) it
covers. Only the size of alerts is limited.

>

Well--you could keep reading the seconds clock until it changes (thus giving a fix for the end of a second) and store the contents of the 200ths-of-a-second counter (or the 60ths/70ths, if you prefer it) at that moment. Then calculate the remainder when the difference between the count "now" and "then" is divided by 200 | 70 | 60. This gives the number of time quanta since the last increment of the seconds clock.

> this is the "normal" way of doing it, but it does have limitations. i think
> the max dialog size is 1/4 the screen as that is all the memory form_dial
> deals with. i may be wrong here, though...

The call to form_dial(FMD_START...) does not reserve ANY memory.
It just remembers the coordinates of the rectangle that will be disturbed.

The final call to form_dial(FMD_FINISH...) likewise doesn't restore
the screen. Rather, it generates an "event".
This event must be picked up by the program by a call to
evnt_multi. The infamous coordinates are supplied to you by the event,
and it is the responsibility of the program to redraw the
affected screen.

The limitation of 1/4 the screen size applies only to form_alert
dialogues. The background of form_alert dialogues is saved
by the operating system, and therefore no events are generated
by this call.

> there is a better way, at least i use it:

I prefer this solution, too.
You can even have sub-dialogues by allocationg a second buffer.

>you don't get the (silly?) growbox/shrink box (my beta testers told me to
>ax them on some code i produced a while back).

The choice to grow/shrink box is independent of the way
you save the background.
This feature is achieved by the form_dial(FMD_GROW/SHRINK) calls,
which can be included or not, regardless of the way you
subsequently restore the screen.

Ideally, the grow/shrink is executed conditionally depending
on a switch that can be set by some preferences-dialogue.

865. Why doesn't this DMA code work?

Newsgroup: comp.sys.atari.st.tech
Date: 1990-12-18 09:27:26 UTC
From: bwhite@oucsace.cs.ohiou.edu
Message-ID: <2717@oucsace.cs.OHIOU.EDU>
Source record: 49603

I'm working on a program that will allow me to read in an entire track of the floppy disk at a time (using the Type III `read track' command) and put it somewhere in memory, where I'm going to analyze it and such, as part of a head-alignment program.

My main problem here is, I can do all sorts of Type I commands which don't require DMA data transfer, but as soon as I try to read something off the disk, ... well, according to the floppy controller all went well; but the data doesn't appear anywhere in memory.

The code is in Mark Williams C. I have a hard drive running during program execution; shutting it off after boot from HD does no good. I would boot from floppy to see if the HD boot program (ICD) is causing a problem, but if I could use my floppy I wouldn't be writing this program!
I replaced the `read track' with a `read sector' command, which I *know* should work, and I use it on side 1, where the head is in perfect alignment. The data still doesn't go into memory.

My code looks like this:

```
readtrack(buffer,track,side)
char *buffer;
int track,side;
{
long buflong;
int dummy = 0;
static int oldtrack;

#define FLOCK (char *) 0x43eL
#define DMAC_HI (char *) 0xff8609L
#define DMAC_MD (char *) 0xff860bL
#define DMAC_LO (char *) 0xff860dL
#define DMAMODE (char *) 0xff8606L
#define DISKCTRL (char *) 0xff8604L
#define DMASTAT (char *) 0xff8606L
#define DMAINTR (char *) 0xfffa01L

buflong = (long) buffer;
pokeb(FLOCK, 0xff);
Offgibit(2); /* Select drive */
Ongibit(1);
if (side) /* Select side */
Ongibit(0);
else
Offgibit(0);
```

```
if (track != oldtrack) {
oldtrack = track;
pokew(DMAMODE, 0x0180); /* Toggle R/~W */
pokew(DMAMODE, 0x0080);
pokeb(DMAC_LO, (int) (buflong & 0xffL));
pokeb(DMAC_MD, (int) ((buflong>>8) & 0xffL));
pokeb(DMAC_HI, (int) ((buflong>>16) & 0xffL));
pokew(DMAMODE, 0x0086);
dummy++; /* A slight delay */
pokew(DISKCTRL, track);
dummy++;
pokew(DMAMODE, 0x0080);
dummy++;
pokew(DISKCTRL, 0x19); /* Command: seek */
dummy++;
do { } while (peekb(DMAINTR) & 0x20);
}

/* The above code works fine. The next code fails miserably. */

pokew(DMAMODE, 0x0180);
pokew(DMAMODE, 0x0080);
pokeb(DMAC_LO, (int) (buflong & 0xffL));
pokeb(DMAC_MD, (int) ((buflong>>8) & 0xffL));
pokeb(DMAC_HI, (int) ((buflong>>16) & 0xffL));
pokew(DMAMODE, 0x0180); /* Removing this does no good either */
pokew(DMAMODE, 0x0080);

/* pokeb(0xff860dL, 0x00); Uncommenting this doesn't help either.
pokeb(0xff860bL, 0x84);
pokeb(0xff8609L, 0x0f); */

pokew(DMAMODE, 0x0084);
dummy++;
pokew(DISKCTRL, 0x0001); /* Set sector to 1 */
dummy++;

pokew(DMAMODE, 0x0080);
dummy++;
pokew(DISKCTRL, 0x0080); /* Execute `read sector' command */
dummy++;
do { } while (peekb(DMAINTR) & 0x20);

#ifdef DEBUG
pokew(DMAMODE, 0x0080);
fprintf(stderr,"DEBUG: ERROR %x FLOCK %d\n",peekw(DISKCTRL),
peekb(FLOCK));
fflush(stdout);
#endif

pokeb(FLOCK, 0);
}

Anyone out there know what's going on?

How about the following (is this legal?)
1. Use Pexec to just load the program in memory and save the pointer,
say 'basepage_pointer', to the basepage
2. Execute the program, again using Pexec. The program then exits
using Ptermres.
3. When finished perform 'Mfree(basepage_pointer)'

This seems to work, but the memory gets fragmented and I still seem
to lose some memory. Therefore: 1. Is this legal?
2. can I recompact the memory so it
becomes contiguous?

Richard Schaaf (rfschaa@cs.vu.nl)

P.S. I will not be at the university for at least 4 weeks, so please
send any reply via email otherwise the article will probably
not be available when I return..... THANKS

Try calling wind_set(WF_NEWDESK, ...). This tells GEM that the desktop is now the object tree you created and will redraw it everytime the desk is exposed. You won't receive evnt_multi messages to redraw the desktop, AES will do it for you!

Sorry, Bill, Dan is right. It _is_ that bad, and there are easy ways to
do it better.

>and it is the only way i know of to use dialogs larger than 25% of the
>screen. unless u can suggest a better approach? i'd gladly change my
>evil ways :-).

Get the size and position of the dialog displayed. Find out the number
of bitplanes used by calling vq_extnd() and looking at work_out[4]
(I think it is 4, but there I might be wrong.). Malloc sufficient space
for your dialog and vro_cpyfm the background to the allocated memory area.
You don't need any video buffer addresses to do that. Just fill in 0L
as the start address in the screen MFDB; VDI will automatically fill
in all the required MFDB parameters for the screen.

Then objc_draw() your dialog and do any form_do thingies you'd like.
Afterwards, vro_cpyfm() the background to the screen again.

This way, you can have _fast_ dialogs in a GEM-compatible way, and
you won't ever have to bother with new screen resolutions or graphic
cards with video RAM that is not visible in the processor's address
space.

>i really do not think this affects most *current* ST owners. and i use line A,

Waouuuuuuu... a REAL programmer... Thanks God, it still exists.
You are perfectly right, this is a complete GEM-routine.
BUT, i am not so happy to see work_out[4]... This last sentence is
not written for you but for Atari. A parameter MUST NEVER BE OBTAINED by
looking in a set of system variables but using inquire's functions like

vdi_what_is_current_resolution(x,y,w,h,planes)

And it is possible to compare the use of Line-A stuff to the old Peek &
Poke.
I hope we will see someday a *nice* Gem...

/Daniel/

Yes. The 20-pin-connector for the second harddisk is not soldered in.

>3) A new power supply might be needed.
If you use a low-power-supply-harddisk, you don't need another power-supply.

>4) I would have to write my own software as HDX will not support
> the second drive.
For the HDX-Software this is true. But: There is a famous harddisk-driver
written by Claus Brod (unfortunately NOT PD) which supports a second drive
on one MEGAFILE-Controller.

>My reaction is: Too much work/risk for me to undertake. I guess
>I could purchase a second Megafile but perhaps I should just save
>my money to buy a better machine.
You need to be experienced in hardware-working for that. But after all
modifications, it's running quite well ! I've modified my own MEGAFILE-30-
controller and it drives now 2 Seagate-drives without any problems. And
the system is running 24-h a day under OS-9 ! Sometimes it takes 4-5 weeks
until i must reboot my machine, so the hardware of Atari isn't bad at all !

Why not try the Third Coast drives - they do allow you to 'plug in and go' with
a second drive from what I've read...

I'm writing a program that uses only AES, and not VDI. When I put up
a dialog box, I save the portion of the screen used with my own copy routines,
and when the dialog finishes, I copy the region back. Everything works fine
except when the user moves the mouse at a later time, a small square the size
of the mouse appears with the standard desktop background pattern. Is there
anyway to avoid this, can I change the buffer used to hold what is underneath
the mouse pointer background?

AAAAAAAAACCCCCCCCCKKKKKKKK! What? How are we supposed to do graphics now? (PLEASE don't say "Use GEM" -- I really don't want to wait till next spring to get some graphics on the screen.) Is there any TT-compatible, acceptable method for producing FAST graphics on the ST? (Preferably one that will stay acceptable.) Or are we all doomed to either incompatibility or slow, creeping death? Perhaps I should read this group a little more closely. This is the first I've heard on this topic...

Maybe I'll dig out my Atari 800...nobody complains if you POKE to the screen on those... :-)

hide the mouse before u copy the screen (before and after)...

and for the rest of u, quit beating me up about 32k. i don't do this myself
(i even checked my last GEM program). i DO do it correctly. my post was done
in haste, admitedly. ALL code i write that absolutely is not tied to some
OS or other dependency IS portable, or at least i strive for it consciously.
sometimes i hack, but believe me, anything i write which i have the
slightest inkling of selling at some point is done to maximize the potential
user base. things i do on usenet generally do not fall into this category.

yes, yes, by all means write your code to be hardware independent. though
i still believe 99% of STs use 32k screen buffers and i suspect this
will be the case for some time. if u want, we can argue that point, though
i think that is a waste of time.

later...

876. RAM expansions

Newsgroup: comp.sys.atari.st.tech
Date: 1990-12-18 21:23:38 UTC
From: billm@CSUFresno.EDU
Message-ID: <1990Dec18.212338.1351@CSUFresno.EDU>
Source record: 49616

I have gotten a hold of an ST second hand. It is a 520, with 1 meg upgrade. The upgrade is an AERCO EasieST Solderless RAM board, and was installed by a shop in San Lois Obispo, CA (That's what the previous owner told me). I have none of the docs for this board. It has 32 sockets, with 18 pins each. 16 of these sockets are populated with 32K 150ns RAMs with 16 pins each. The extra 4 pins that are open on the sockets all halve solder traces connected to them, so it seems likely that this board can handle larger (18 pin DIP) chips.

My questions:

Does Aerco still exist, and if so, where can I get a hold of them?
Is any-thing more than plugging in 16 more 32k chips required to take my machine to 1.5 meg?
Will using faster RAM speed up any operations that use the memory in the card?
Can I replace the 32k chips with 64, or even 256K chips (all of which are very inexpensive these days) to go upwards toward 4 meg?
Any help will be greatly appreciated, please respond via e-mail.

>TT-compatible, acceptable method for producing FAST graphics on the
>ST? (Preferably one that will stay acceptable.) Or are we all doomed
>to either incompatibility or slow, creeping death?

u know, this was my initial reaction, when i first heard the TT would not
support line A (which i use because it is extremely easy to program
graphics, once u make a few trivial assembler functions to do put/getpixel
and drawline). in fact, i just posted a mono gif viewer yesterday which
uses linea 0, 1, and 3. it also will NOT run on a color monitor, tho that
was the point, afterall. i own a couple of STs (including a mega4) with
both monitors, tho i greatly prefer the really excellent mono monitor.

i can just see the screams of anguish THAT will cause :-) :-) :-) :-)

still, it is FREE (including src) so if u don't like it, TOO BAD (expletive
deleted). don't use it, or post a version (including src) that does the
same and runs on ST/STe/TT/?T. since i am not selling this, i really don't
care that it won't work on the TT (or ST with overscan). if/when i get a TT
or BIG monitor, i will program for it. maybe the people howling at me
about portability will send me one gratis :-). my stuff runs on >1 million
STs. i can live with that. my next COMMERCIAL code will run on all systems,
IF it makes sense from a marketing perspective (it generally does, BTW).

the advice i gave on dialog boxes is sound. i will conceed that it is not
entirely portable, tho i'll stand by it nevertheless. i suspect it is the
basic idea that the person was looking for, which is what i presented. it
is up to him/her to fill in the blanks after that. i am glad this oversite
was pointed out, though i resent being called a lousy programmer because
of it. i GAVE this community a working nroff (i COULD have SOLD it to you).
and yes, it is not a complete/perfect nroff, but i use it daily and format
reports for my customers with it (files run UNMODIFIED under real unix)
as well as 100's of man pages for my system.
and it is FREE with NO RESTRICTIONS so u can do whatever u like with it
(no, i won't say it :-). i just added hyphenation as well, and am
planning a rewrite soon, complete with (non-GDOS) fonts for italics and

BOLD in conjunction with man(1). this nroff is being distributed with Minix as well (and ported with extreme ease, BTW, eventho i do not even have a running minix system) and do not receive (nor wish to) a penny from its sale.

i was going to write (and distribute, src included) a tcsh(1) using MiNT as well. i am NOT going to worry about it not running on some systems. you get the src, you fix it yourself. the only reason i am forced to write this (for myself) is that u can't get the src to gulam and fix it (tho i can't complain about something free which i use regularly - in fact, just the opposite).

my guess is that >95% of the people reading this group have no intentions of selling their work. those that do plan on selling, will find out what portability really means when they get complaints. besides, i see them as potential competitors :-). and NOBODY should complain about free software they can't use. i also encourage everyone to post source code so that if someone does have an odd configuration, they can fix it to work (if they want to take the time and have the propensity to do so). i generally ALWAYS post source. others cannot make this claim for one reason or another. i share my efforts...completely...

no need for followups on this. the issue is beaten to death...

(ok, i have calmed down...it is good to vent the spleen every once in a while and i was pissed off)

>of the mouse appears with the standard desktop background pattern. Is there
>anyway to avoid this, can I change the buffer used to hold what is underneath
>the mouse pointer background?

While copying the screen, you must temporarily switch the mouse off,
like in:

```
copyscreen(from,to) long from,to;
{
register long *x;
register long *y;
register int i;
x = (long*) to;
y = (long*) from;
i = 8000;
graf_mouse(M_OFF,0L);;
do{ *x = *y;
x++;
y++;
}
while (--i);
graf_mouse(M_ON,0L);
}
```

Note for Swedish flamers: no, I do NOT intend to port
my programs to later versions of the Atari.
It is my decision to sacrifice portability later
for efficiency now. I am aware of the fact that it
is harmful.

ADDR is a macro which takes an address and breaks it into 2 16 bits numbers.
This is essentially a hangover from PC-GEM days. If your GEM libraries are
correct, you can lose the ADDR

> Incorrect parameters to form_do(). What exactly is this
>function expecting? Is there a limit to the size of box form_do() can
>handle? (Someone mentioned 25% of the screen. I need a bigger box.)

(This is from memory only). I think you pass two parameters. The first is the
address of the resource tree. The second should be zero unless your dialog has
editable text objects, in which case it should be the resource index of the
editable text object that the cursor is to be placed at. I believe some
documentation tells you to pass -1 instead of 0 if no editable text strings are
used, which is incorrect (I hope I got this the right way round!). I don't
think there is a limit on size as long as it will fit on the screen. 25% is the
size of the redraw buffer and applies to menus and alerts only. When your
dialog is removed, a series of redraw events will be sent to the owner(s) of
the windows underneath. Note that having too large a dialog may restrict the
resolutions in which your application will work.

882. form_dial(0,...) ??

Newsgroup: comp.sys.atari.st.tech
Date: 1990-12-19 11:03:37 UTC
From: stefan@hpbbi4.BBN.HP.COM
Message-ID: <7120006@hpbbi4.BBN.HP.COM>
Source record: 49622

Does anyone really know what the aes call

form_dial(0,...)

does. The doc tells me it reserves area on the screen ?!.
First time I thought the window rectangle lists will reflect this.
So it should be possible to update a window which is under
the reserved area ? This is not true (at least on version 1.2).

What is the real meaning of that call?
Which consequences has this call?
Which consequences has omitting the call?

Just to be complete

form_dial(3,....)

forces a redraw of all windows which intersect with rectangle
given with form_dial(3,..).

Thanks for your help

Stefan

Note that the 16 256K drams are in the bank furthest away from the the edge card connectors.

When installing the 1 megabit rams, remove the 256 K chips and put the 1 megabit chips in the bank closest to the edge card connectors.

The address for Aerco is

Aerco
Box 18093
Austin TX 78760
512-451-5874

I have no idea if they are still in business or not. I guess I ought to call them and see.

If anyone has additional information about bringing one of these boards to 4 megs please let me know thanks...

btw.. I have no affiliation with Aerco and if your machine dies when working on it, I disclaim any liability. Of course if any of this works then it is because of me. Natch...

The question is, of course, is how much faster is your hard-wired
routine than using a software-blitter? It's better to fix the slow ROM
code in one place than fix it in all your programs.

>on this topic...

Ahem... use GEM 8-) Yes, there are ways to have _fast_ GEM-compatible
graphics. The idea is to build up your graphics in a non-visible
background buffer. There, you can use any kind of hand-coded,
optimized graphics routine - as long as you use the GEM standard
format in the background buffer (no interleaved bitplanes). When
you have generated what you need, vr_trnfm() it to the device-
specific format used by your current screen driver and use
vrt_cpyfm() or vro_cpyfm() to blit your graphics to the screen.
This should be fast enough for most applications except animation.

By the way: If you fool around with VDI a bit, you'll notice
soon that it isn't as bad as most people think. The only part of it
I don't like that much are the font functions, especially finding
out reliably if some font is proportional or which default sizes
you have. Hopefully, FSMGDOS will improve things now.

Your 1040 is definitely a neat package! My 1040 has a brand new Tower-
housing to fit all extras inside, including two Seagates.
My ST also has two drives, Spectre GCR and HyperCache, but it also
has 4Mb RAM expansion and Vortex ATonce AT-emulator.
You should get a tower also!
What is ST-QL shifter???????????
If you are planning to get the Delta Modul, your HyperCache will
become an orphan, hope you'll find a nice home for it...snif.

Where are you planning to get 68030 fitting to ST???
Do you think that Gadgets by Small gets their thing working?

By the way, I have a german friend, a real electronics wizard.
His ST has 4Gb RAM (!!!) and four parallel 68030 running over
30 MHz!!! I have several times asked him to go to markets with
these superior upgrades, but he says "never, I'll lose my privacy that way".
Hope someone else can make these things work someday...

Oh, sorry! I almost forgot it! There is the HyperCache 030, it has
68030 with cache, but it is not compatible with all software, so forget
it again (at least I will!)

891. Re: Closing AES boxes interfering with VDI drawing

Newsgroup: comp.sys.atari.st.tech
Date: 1990-12-19 22:11:05 UTC
From: mintha@unixg.ubc.ca
Message-ID: <1990Dec19.221105.5886@unixg.ubc.ca>
Source record: 49631

On a related topic, does anyone who is using gcc know how the asm
command works? I can't seem to find any information on in it in the
info system in emacs. I want to do a loop to move the screen up one
line in assembly, but I can't seem to get it to use labels.
I want to do something like this: (somewhat simplified)

```
asm ("movel %0,a0" :: "a" (scrbase)) /* load a0 screen adr */
asm ("movel %0,a0" :: "a" (scrbase2)) /* destination (1 line down) */
asm ("movew %0,d0" :: "d" (size)) /* number of long words */
asm ("loop: movel (a1)+,(a0)+") /* copy the memory */
asm ("dbf d0,loop") /* --1 and branch */
```

My assembly is a little shakey, but I was able to get it to work with
megamax C, but the above GCC version won't work.

No, I was talking about commercial programs like TurboST and QuickST,
that replace the ROM routines. They are sometimes not completely
compatible, but it seems that if you're doing "ordinary" GEM programs,
they do pretty well. And you can just program in GEM and not have to
drop into assembler all the time.

>(*Have* they significantly sped-up AES or VDI since v1.0 of the ROMs?

Well, from what people said, removing the line-F traps and putting in
subroutine calls made things faster. But they certainly didn't go in
and rewrite the VDI routines in assembler :-(Fortunately, there are
at least 2 companies happy to exchange your cash for their solution.

Are QuickST and TurboST available in Europe?

896. ICD Hard Drive Stuff

Newsgroup: comp.sys.atari.st.tech
Date: 1990-12-20 03:43:33 UTC
From: weiner@terminator.cc.umich.edu
Message-ID: <1990Dec20.034333.2782@terminator.cc.umich.edu>
Source record: 49636

I have a home built hard drive system that uses an ICD host adapter and ICD driver software. I also have a Supercharger PC emulator. Shortly after I got the Supercharger, I found out the hard way that SC didn't behave properly with the ICD write cache. Everything would appear fine, but the SC would never purge the cache. When the system was shut off, the last thing I wrote to the disk would disappear. The obvious solution was to disable the cache. This works, but I miss the cache, especially in ST mode. Does anyone out there have any ideas on how I can get the SC to automatically purge the cache? If anyone reading this group is associated with ICD or Talon, I'd really like to hear your input. The only other solution I've come up with is to read a large file right before shutting down. This forces the cache to purge. Unfortunately, this is dangerous as I only have to forget once, and I could lose a large data file. Besides, I'm usually not the one to use PC emulation. Also, if the machine crashes or if there's a power outage, this method isn't effective. I am looking forward to hearing any replies that could help. Thanks.
Terry
PS- Please respond directly to me as I am incapable of reading this newsgroup. (Thanks, Jeff, for posting this)

Here's a repost of my repost on installing the JRI SIMMs board. I installed 4MB in my 1040ST. Everything works, the memory is usable with Spectre and everything else. Once in a while, the 1040 has problems booting, but if I lift it slightly off the desk and drop it, it works fine. Note that the prices I have quoted are much cheaper now, probably $35-40 or so (for the SIMMs)

---jb

Here's a summary of my recent adventure expanding my ST's RAM to 4MB using the JRI SIMMs board.

John Russell Innovations
PO Box 5277
Pittsburg, CA 94565
(415) 458-9577

I bought 4MB of 1MBx8 80NS SIMMs from some vendor (I forget) but browsing through the current MacWeek, I found the PSI ad:

PSI, Inc. (800) 622-1722, for $59.50 per MB, you defintely need low profile SIMMS. By the way, the JRI board was $125, so the whole thing can be done for about $350-400.

Here's how it went for me:

The JRI kit arrived and even included some jumper wires and some solder! There are 4 different sets of instructions that you must choose from, depending on your particular ST's motherboard (works for 520STs also, by the way). The

differences between the boards are clearly shown. I found that the instructions were a little vague about a couple of things, for example, the instructions keep refering to top,bottom,left,right sides of the shifter board when the proper orientation of the board is never shown.

Basically you have to remove 6 resistors from
the motherboard (only 3 if you're just going to 2.5MB) and put in a total of about 10 jumper wires, one of which is a pain because it is a jumper to pin 61 of the MMU, which must be soldered UNDERNEATH the motherboard and then attached to the JRI board. I had a couple of problems with the upgrade, first problem was that the jumper to the MMU that runs under the motherboard got shorted by some of the soldering points under the ST. I solved this by using electrical tape to stick the jumper to the backside of the motherboard in safe fashion. You also have to remove the Shifter chip, which is inside a square tin housing. You then put the chip on a supplied board, which then goes into the socket (thank god a socket was used!) left by the now vacant Shifter. This board has space for 2 shifter chips, which means that if you buy the optional second shifter (can get them at any Atari service place, I guess) you can get 4096 colors instead of the 512 on a regular ST (I haven't done this yet) Anyway, I accidentally plugged the shifter board in wrong, it's difficult to see what you're doing here--not much space. Next problem was that the bottom of the shifter board was shorting out with other components underneath it. I used more tape to fix this. This problem was weird because the machine worked in monochrome, but would bomb out in color. Luckily, I figured it out. Oh, by the way, I noticed the problem with the shorted MMU jumper because the machine only recognized 1MB of RAM. The third problem was where to put the board and still be able to shut the ST's case. I found the best way was to run all the wires through the shield that goes over the power supply (I had to bend the shield for this) and lay the board between the power supply shield and disk drive ABOVE the big tin shield. I put the board in a plastic bag to hopefully avoid any moisture or spill problems.

All in all, the thing works!!!
The instructions were a little vague in the areas I touched on above, and I wouldn't recommend doing the upgrade unless you are willing to rip your machine apart. A couple of times I thought I had broken my machine, but carefully going over all of the connections helped me find all of the problems.

By the way, you only need 120NS SIMMs, not the faster ones I got, but the savings for the slow SIMMs are probably minimal.

Good luck if you decide to go for it!

Using the vex_motv function is actually not really ok. If the mouse
moves while this function is changing the vector, then the ST crashes
(at least with TOS 1.0). One should prevent the mouse to move by
setting the system variable which says wether the keyboard interrupts
must be handled or not. Unfortunately, I can't remember the location
of this variable.

I recently purchased a Zram 4-D ram upgrade for my ST. I am pleased with the upgrade, it appears solid and has worked fine in the 520STFM I have it installed in, but there are a few cautions.

The company that manufacturers the board offers a one year warranty for the board if they install it. However, a warranty is only as good as the company that backs it up. Simply put, their customer service is piss-poor. When I purchased the board, I was assured the 4 meg board fit into my 520ST old style machine. I shipped my machine to california, where they proceeded to stuff the 4meg board into the machine. The machine was returned to me, and promptly failed a couple of days later. A call to customer service informed me that the 3-D 4meg board was not designed to go into the old style 520 (somehting the salesperson assured me, at WAACE in October, that it did.). I shipped the 520ST and the STFM to California, where, having forgotten my original instructions, installed the RAM chips on the top rather than the bottom of the board, thereby requireing that I take the machie to a local dealer to get the board upgraded to 4meg from the current 2.5 meg.

So, if you buy your board, buy it from and have it installed by a dealer. Don't ship it to Zubair. The entire debacle was entirely Zubair's fault (first they sold me the wrong board, then they installed(!!!) the thing, and their only offer of recompense for my trouble was that they would re-install the board for free, not even pay for shipping the things!

I find that many ST products are sold by people who may be having a hard time of it, as there aren't alot of ST's in teh U.S., and many take their frustrations out on their customers (Toad, Best Products, and Gadgets are of course exceptions to this rule, but then, I hear they're all doing quite well so they have no reason to be unfriendly...)

> of the mouse?

I beleive there are a couple of ways. The way I did it in a recent
hack job :-) was to use the VDI mouse exchange vector system call
the curret x co-ordinate from the driver appears in d0 and y in d1
change these to your new location and vector through the address
returned originally by vex_motd (I think thats the call name I
haven't got my ref manual here). Someone has mentioned that the
mouse and kbd exchange vectors are semi priveleged (for aes use only)
but my DRI developers kit for GEM 3 makes no assertions of this
nature (I trust DRI when it comes to gem :-) anyway you need to
be VERY carefull with this call.

1. The mouse vector MUST be restored before you exit your program
otherwise when TOS releases you programs memory and zaps it the
routine you specified in the mouse call disappears and VDI vectors
int thin air next time it execute the mouse driver, This applies
to error and exception bomb outs too, so either your programs must
be exception proof or you must handle exceptions yourself. (ATARI -
I think you missed this one in TOS1.4 bomb handler)

2.) The routine inserted should be short: the mouse handler seems to be
called at EVERY vbl rather than when the mouse position changes
(only drawing does not occur if the mouse has not moved) *Atari should
fix this too it is a waste of time to execute the mouse driver if no
movement was detected by the IKBD*

There are probably some other gotchas but I can't recall them right
now, but use of the mouse exchange vector (boy will I get flamed now)
is probably ok if the above rules are followed and the handler is only
installed while the mouse is in your space ie over your window (
a watchbox will be needed) unless of course (in apollo terms :-) you
"borrow" the screen for a bit (Really love that term :-)

This would be nice - the ST's graphics really haven't improved a whole lot
in such a long time. Even the 12 bit palette on the STe, as nice as it is,
doesn't compare to the 24-bit palettes on PCs with 8 bitplanes, or the Macs
and their 24-32 bit cards. I don't mind the palette size so much, but the tiny
number of bitplanes is a real drag. 12 bitplanes would be about satisfactory,
I guess. (Although I guess that makes for pretty huge color-lookup tables. You
don't *need* the CLUT if you have a 12 bit palette and 12 bitplanes, but it

makes it easier to achieve nifty color scrolling effects that way... }-)

Two questions, just 1 answer - gcc uses 32 bit ints by default. The 68000 works best with 16 bit ints. The PML16 library was compiled with the -mshort option, and is for linking with other objects compiled that way. They will typically be smaller and faster than the 32 bit default libraries. They also typically cause massive headaches when porting Unix code to the ST, but you have to expect problems, eh?

>soon that it isn't as bad as most people think.

I can confirm this I once made a set of routines to give formatted text
on the screen using LineA code. Later I rewrote the stuff to use only VDI
routines. It turned out to be faster to use the VDI instead of the LineA?

Never bothered to figure out why this difference, but I learned to handle VDI
calls and still get reasonable speeds. The trick is not to use them to much be
only when you really need them.
This is ofcourse a useless statement but if you program carefully VDI is fast
enough for general purposes.

Source record: 49502
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

I now have gotten the full gcc 1.37.1 cross-compiler running on our Sparc
at work, with only one exception... I can compile with the -gg option fine,
but sym-ld always core dumps when I try to creat a .sym file! The cross-compiler
seems to work great, I was able to compile gdb.ttp without a hitch, I just
can't run sym-ld on the Sparc!!!

I also patched the gemlib src to include the vdi escape sequences that it
has been missing. I guess I will need to get around to sending the diffs
into the archive in the next few weeks. This gives you v_curhome, v_curdown
etc... which wasn't in the original gemlib stuff.

If someone has a version of sym-ld running on a Sun-4, please E-mail me!!

From: klute@tommy.informatik.uni-dortmund.de
Message-ID: <2887@laura.UUCP>
Source record: 49499

Does anybody have experience with MTools?

I would like to write files to a floppy on my Sun Sparcstation using MTools
and read them with my Atari ST. However, on the ST I can read only the
first one or two sectors, then the last portion of the file is repeated,
then a read error occurs.

On a PC reading the file is no problem. (No, I did not touch the PC myself
- I had someone doing that for me :-).) Consequently MTools works ok but
something is wrong at the ST side.

Any hints?

You guessed. I asked Aerco at one point. They said they could FAX me the instructions and that it required trace cutting. That first bank is designed for 256K DRAMs, which aren't pin compatible with 1M DRAMS. They said that the trace cutting necessary was to rewire each socket in some special way.

> to load the accessory. I assume that for accessories I need a different
> startup module (?). Can anybody tell how to do this (I don't see accessories
> mentioned at all in the GCC docs).

the gcc startup automatically detects if a program is being run as an
ACC, but you have to help it a little bit with its stack+heap area.

the convention is that the user has to set two variables:

_heapbase to the botom of the stack+heap area
_stksize to the size of this area

here is an example:
define the following global variables in your file, adjusting the
size as appropriate.

```
char _stack_heap[1024];
void *_heapbase = (void *)_stack_heap;
long _stksize = sizeof(_stack_heap);

main()
{
/* whatever */
}
```

at startup then, the stack will be set at the top of this area, and
the heap at the bottom, and the two grow towards each other. You can
do malloc()'s from this area in your ACC (notice malloc() and not the
tos's Malloc()).

cheers,

re: LINEA considered harmful

I've been unable to find all the relevant postings on this topic, maybe they didn't all make it here. The gist of it seems to be that the TT doesn't support the linea functions so any programs that use them directly will automatically not work on the TT. I hope that's an accurate summary. If not, I'm sure you all will let me know about it! :-)

Well, last night I finally got around to reading my Neodesk 3 upgrade manual (as opposed to gleefully playing with the program). There's a nice big paragraph in there about how Neodesk 3.0 bypasses the horrendously slow VDI functions and makes use of the quick linea functions instead. But wait a sec, Neodesk 3 runs on a TT! Something here does not add up. (Not to mention that I doubt Gribnif would head down the linea path if it was going to be obsolete.)

Well, one other point of commentary. I *still* find incompatibilities with the software blitter I use, and I have the latest version. So sometimes I must turn it off. I'm glad Neodesk stays nice and snappy when the software blitter isn't there.

>You should get a tower also!

Well, the whole purpose of the exercise was to see what could be fitted in the standard box, so a tower could not be considered. The only shielding I had to remove was the thin bit under the disk drives, the lower drive shields out most if not all of the gap. BTW I looked inside a STacy the other day, to fit anything extra in there would need throwing out the main board :-)

>What is ST-QL shifter???????????

It is the hardware part of the ST-QL emulator (from Jochen Merz Software and/or QJump). The shifter board provides overscan capabilities, though I think they're still working on the drivers for that aspect. It's main purpose is to provide 512*256*4colour screen for running standard software under the emulator (multi-tasking OS, ST device drivers, and software). BTW if anyone out there is still waiting to hear from me about this I shall be preparing a review as soon as I get the custom addressing chip together. (No I'm not rebuilding GLUE, only patching).

>If you are planning to get the Delta Modul, your HyperCache will
>become an orphan, hope you'll find a nice home for it...snif.

Anything goes, it can be fitted to virtually any 68000 computer but the GAL addressing has to be changed to redefine the memory map. Have to do that one anyway for custom ST address ranges. As for the Intel/Motorola hybrid board, it would need to have a 68030 and fit a Mega STE.

>Where are you planning to get 68030 fitting to ST???
>Do you think that Gadgets by Small gets their thing working?

According to recent posts it has been seen demonstrated, it'll whip the socks off anything. It looks _really_ good but there's just not room in a 1040 the way the board is designed. Does anyone know whether it can be fitted to a Mega STE?

>By the way, I have a german friend, a real electronics wizard.
>His ST has 4Gb RAM (!!!) and four parallel 68030 running over
^^^^^^^
Was that 1GB per CPU or some other configuration?
If you know any more about any of this, then do tell (if it's for real).
What OS does he use and what does he use his computer for mainly?

Oh, one more question:
Does anyone know of an amiga emulator for the STE range?

Seasons greetings,

From: johns@maccs.dcss.mcmaster.ca
Message-ID: <2772E81F.19805@maccs.dcss.mcmaster.ca>
Source record: 49510

I don't know how popular they were, but here in Canada Atari used to sell the 520 with a monitor model PS3000. The PS3000 had the SS drive built in right into the monitor case, right below the picture tube. Does anyone have experience with upgrading these from single- to double-sided?

As a special favour to a friend, I've taken it upon myself to upgrade his system, starting with the floppy. But both the monitor and the floppy connectors are on one board and now I'm confused. If I can't replace the mechanism, how about adding an external, but the *external* has to be drive A. Is this possible?

I've thought of one other option. How does the Atari policy on upgrades go? What if I wanted to trade the monitor+drive for and an external drive and monitor?

Thanks for your advice.

ICD does have a Tape backup device, and that comes with software, I don't think that ICD will just sell you there software, they will want to sell you the drive as well, I have never heard of any one else doing one..

I wonder if maybe people have gotten LINEA and LINEF confused?
LINEF (undocumented) functions are not supported on the TT, because these
opcodes are used in the 68020/30 for coprocessors. But Motorola has not
assigned anything to the LINEA operations, so I see no reason Atari would
have dropped their support in the TT.

I don't know one way or the other on the TT and LINEA, but I wonder if
others might have confused the LINEF changes on the TT and concluded
that LINEA was dropped too.

Could someone at Atari clarify this?

The problem should be that you don't hide the mouse before you make any
changes to the screen. A procedure that should work is the following:

1. hide the mouse (AES: graf_mouse(M_OFF, 0L), or
VDI: v_hide_c(vdi_handle)
)
2. save the screen-area that the dialog box will cover
3. show the mouse (AES: graf_mouse(M_ON, 0L), or
VDI: v_show_c(vdi_handle, 0)
)
4. display & manipulate the dialog box
(objc_draw(...) and form_do(..) or evnt_multi(...))
5. same as 1
6. restore the screen-area saved in step 2.
7. same as 3

Hope we helped.......

I am also using Mtools on my local un*x box and had the same problems
that you mention (My Mtools was an older version, not 2.0). Further
investigation showed, that Mtools only wrote and updated one File
Allocation Table (FAT). While PC's have not trouble with this, the ST
does. My sources of Mtools had a define in it to allow writing of both
FAT's. After recompiling the Mtools worked okay.

Hope, this helps.

The time of day is read by TOS from the keyboard processor. I believe that the time is packed into a single 32 bit word to match the way MS-DOS handles the time stamp for files.

It is possible to get the time of day from the keyboard to the nearest second. This requires patching some interrupt vector and writing a routine to send the time request packet to the keyboard and receive the time packet. Pages 67 through 84 in the book Atari ST Internals (from Abacus Software) details the interface with the ST keyboard. It seems I read somewhere that the keyboard processor keeps time to milliseconds, but cannot find it now.

Hope this helps.

Hmm! didn't know that one (I have TOS1.4) and have not seen this behaviour,
what exception does it cause ?. I have a pile of interrupt routines running
and occasionally get a spurious-interrupt exception generated (lotsa bombs).
I would have thought that this change would have been atomic.

Can you say B.U.G. ?????

BTW - From memory the mouse vector is stored in a documented place
in the LINE-A variable set so I spose you could be more atomic about it
and do it yourself there (At the risk of being TT incompatible I guess)

The define's name is DUP_FAT. Just compile init.c with -DDUP_FAT.

I now that alot of people out there have put those in, my question is
Do you get a connector that allows you to hook up any SCSI drive off
the back of your Mega? Iknow that it should work if the host adapter follows
the starndard SCSI implementation, however which one will allow you to use a
17 foot scsi cable, or multiple devices off an internal HA? Has anyone done
any similar configuration?

I think that reposting to the net is appropriate.

To clear up any confusion, when we talk about line-A we're talking about graphics. Line-F was a hack in the ST ROMs to save space, and that's not what we're talking about here.

The blanket statement "Line A doesn't work on the TT" is actually a little misleading. The actual statement from Atari is more like this: "Line A is maintained for compatibility with existing programs only, and should not be used in new programs, and will not be maintained for new features of the ST/TT line of computers."

This "new stuff not supported though line-A" is already in evidence in the TT: you can't use line-A in 256-color mode, because you only have access to four color bits. New programs should not use line-A.

If you use VDI correctly, it is no slower than line-A. This is obvious when you realize that line-A is just a back door to the same routines that the VDI uses! There is a little overhead from VDI, but it's small compared to the time to do anything remotely complicated, like drawing a line. Two things can make VDI seem slow: using clipping when it's not necessary, and using some versions of GDOS. In the latter case, it's GDOS's fault, not VDI's, and newer GDOSes are faster.

The cables have to be short enough, as their buffering is very bad.
Otherwise, I don't see any problems.

If so, do I have to alter the dip switches somehow?
Normally harddisks are put on ACSI-Device #0, so you have to
adjust one of them to another address. I don't know much about
the SLM, but it sounds obvious to me that is relatively useless w/o
harddisk, so I'd say it is already on another address. To be on
the safe side, read the appropriate paragraphs of the manual.

One question...

What is the most recent version of GDOS? I'm using version 1.2 and it
does slow screen graphics down. It's most apparent in the zoom boxes.

I don't know the answer to your question, but I have heard of some
problems with it. Sometimes the external Acsi connection is rendered
useless for the laser printer etc.. FYI, SCSI cables are at most 6'
(six feet) long, with short stub connectors extra (6" <six inches> or
so, I don't remember this spec so well), set up as a bus.

e.g.

|--------|--------|--------|--------|--------|-------|-------|

(where '|' is a stub connector and '---' is the cable, 8 devices,
including the host adaptor max)

So scale back your expectations a little ok? 8-)

I jumped the gun: the "new GDOS" I referred to isn't actually available yet. You may have heard about it in reports from COMDEX and the Dusseldorf Atari Fair where it was shown on the TT.

If you're desperate for something faster than GDOS 1.2, you could try G+PLUS, which is a GDOS workalike from Germany (I think); it is faster, but not complete, so it's possible that not all drivers and programs will work correctly with it. This is not an endorsement of G+PLUS from Atari; I just happen to know about it.

G+PLUS is a commercial product of Codehead Software, written by
Charles F. Johnson and John Eidsvoog... (I can only hope Charles doesn't
read this... :)

G+PLUS is a faster *and complete* replacement for GDOS. Anything which
uses GDOS will work faster and better with G+PLUS. Unlike GDOS, G+PLUS
is a fully supported product. Among its advanced features is the ability
to choose among several ASSIGN.SYS files, and to re-load a different one
at any time.

G+PLUS should be available at your "local" Atari dealer for about $25.

BobR

(My God.. you'd think Atari would be a bit more knowledgable about the
world outside of Sunnyvale...)

I assume Allan meant AMCGDOS, the GDOS replacement from Germany. This was originally written as a faster version of GDOS and is now, I think, supported by Atari Germany. It has a few enhancements over the Atari GDOS, such as support for Intel and Motorola format fonts. I've not come across any incompatabilities myself, using it with the Epson FX and PostScript drivers supplied with Timeworks 1.12 and a variety of programs - Degas, EasyDraw, Timeworks, and assorted others. Using the Quick Index program, it results in only a small deterioration in speed. This is compensated for a bit by its speeding up of the open / close zooms.

943. ANDF

Newsgroup: comp.sys.atari.st.tech
Date: 1990-12-30 20:27:53 UTC
From: ericco@ssl.berkeley.edu
Message-ID: <ERICCO.90Dec30122753@sdaf1.ssl.berkeley.edu>
Source record: 49533

I saw an article recently about Architecture Neutral Data Format (ANDF) which looked quite interesting. This is an intermediate language between source code and machine code that is machine independent. The article suggests that future compilers could consist of two parts: source to ANDF, ANDF to machine code. The idea is that ANDF would be difficult to reverse engineer (to protect software producers) and would allow allow machine independent software development. Thus, a company like Lotus could expand into the ST market without a heavy cost. Or, ST developers could reach elements of the IBM market.

hmmm,
Eric

Actually, the correct values are 6 and 0.1 meters, respectively.
(I cheated, however -- I looked it up in the ANSI standard).

Whether or not this works for your drive and controller is left as a
exercise for the student....

G+PLUS isn't really a German product, I think. It comes from some US
software house and is being imported to Germany by Bela. AMCGDOS, however,
is fast and from Arnd Beissner, a German VDI expert. New on the scene
is NVDI, a GDOS with an integrated VDI screen driver (very fast and
very clean; will be the successor to Turbo ST in Germany).

Essentially correct. This is a development of the Open Software Foundation. It's in a feasibility stage right now; we have yet to announce the chosen technology (out of 3, I think, submitters) and bring it out. Don't hold your breath.

> Thus, a company like Lotus could expand into the
>ST market without a heavy cost. Or, ST developers could reach

Things being what they are, the initial implementations will probably be targetted to Unix (or at least Posix) platforms.

949. Host-adaptors

Newsgroup: comp.sys.atari.st.tech
Date: 1990-12-31 09:26:15 UTC
From: ripley@opal.cs.tu-berlin.de
Message-ID: <RIPLEY.90Dec31102615@troll.cs.tu-berlin.de>
Source record: 49538

Hello.

I am in the process of switching from a c't-harddisk to a
regular one and I will need a ACSI-SCSI adaptor very soon.

The only problem is, I know next-to-nothing about these beasts.

I've heard good things about the ICD-advantage and that the BMS2000(?)
is the only one to support a certain Seagate-drive with fullspeed.

As the latter problem isn't one for me, I'm tending towards the ICD
at the moment.

Could you fill my knowledge gap about these things, mainly about
different ICD-models and price differences ?

What I need is ACSI-through to connect more devices (SLM et al.)
and SCSI-out to connect another drive eventually. The ICD's
having an internal clock is quite nice, but it makes them
relatively expensive as well. Is the ICD-software suitable
for a removable harddisk (SQ 555, aka. Megafile 44) ?

Thanx,
RIPLEY

951. hard drive problems

Newsgroup: comp.sys.atari.st.tech
Date: 1991-01-01 01:01:13 UTC
From: rdf@pinet.aip.org
Message-ID: <1991Jan1.010113.20800@pinet.aip.org>
Source record: 49541

I am using a BMS 100 drive adaptor and an adaptec 4070 controller with a Seagate RLL 277 65meg drive. The drive recently started to give me some trouble so I bought a second one. I am planning to get the original one fixed and would like to use both at once. Before sending it away I thought I would try seeing how both work together.

I tried using Atari's HDX 3.01 formatter to check on the second drive, but it only sees unit 0. I have the address jumpers set correctly on the two drives. In addition the AHDI autoboot program does not install any of the logical partitions on the second unit. Berkely supplied a program called "INSTALL" which does let GEM know about the second unit, but I thought the autobooter would check for all active drives.

Does anyone have any suggestions on suitable software combinations for formatting, installing and booting up the second drive?

In addition I am having several intermittent problems. First the drive does not always initialize properly when first turned on. I must power down the drive unit and turn it on again. Second I get occasional alert boxes when doing file operations stating that Drive C is damaged. Most of the time this causes the system to freeze up. After rebooting the same file is ok. This all happens with the new drive. Is the new drive defective? Or is something wrong with the BMS board or the controller? Are there any tests that can be run to isolate the problem? I would like to get the issues resolved before the warrantee on the new drive expires.

- Seagate...don't recall the model no.). I've had this setup about two years.
- It has always been noisy...emits a continuous high-pitched whine which I have
- always assumed was a fan (although I don't know for sure that it even HAS a
- fan).

- Anyone know anything about these configurations? Are they usually noisey?
- Can anything be done about the noise? For instance, should I change the
- fan (assuming there is one) to a quieter one? Is there a plug-compatible,
- quieter replacement? Have I exceeded the threshold for dumb questions yet?

I've had an ICD FaST case with a Seagate 157N-1 for about a year and
a half (installed by Joppa Computers). The noise, fan or drive,
isn't bad; in fact, other HD owners who have heard it say it's
quieter than their non-ICD drives. It may be that the drive is
noisier than others or that ICD used a different fan in your model.

953. Reading Roland W-30 disks on an Atari-ST

Newsgroup: comp.sys.atari.st.tech
Date: 1991-01-01 13:29:42 UTC
From: dc@presto.ruhr.de
Message-ID: <1010263@presto.ruhr.de>
Source record: 49543
Cross-posted to: comp.sys.atari.st.tech,rec.music.synth

I need to transfer samples from a Roland W-30 Music workstation to another sampler. The W-30 can't do MIDI sample-dumps so I'm trying to get the samples off the disks. The disks are formatted DS, 80 track, 9 sector and they are readable (with a disk monitor) on an Atari-ST. Does anyone know the exact format of the W-30 data disks ?

I own two ICD Host Adapters. If you plan on buying a new ICD Advantage Host Adapter, TRASH THE SOFTWARE! The programs are really poor. They don't support SASI devices anymore, and you can't enter your own HD data for off-brand drive mechs. I use the Supra software with my Advantage ST.

(Sorry, I planned to E-mail this, but I lost the original address)

Yes, the 2.5 one should work for you. The 4 meg one WILL NOT work. I have returned mine and am waiting for the 2.5 in exchange. The 3-D/4MEG works, but you can't put the back on at all, even with only 2 meg installed. It is just too big for your machine.

You want the CO25912-38, not the CO100109-001. The later can only address up to 1 Meg. and is only in the newer machines. I don't know about the -A, but it seems ok.

My 2 meg board should be here in another week or so, I can say for sure then, but I am reasonably certain it will work now.

If you want more 'help' with the Zubair board, just ask. (E-mail's best)

From: alex@hpgnd.grenoble.hp.com
Message-ID: <17750003@hpgnd.grenoble.hp.com>
Source record: 49546

Hi and Happy New Year....

My STE definitively refuses to set its Date to any day
after the 31 december 1999.

I have tryied with either GEMDOS call TSetdate() or BIOS (or XBIOS?)
call settime() with the proper bit structure.

There is no problem for any date below year 2000,
but it seems impossible for any other date.

Has anybody experienced this problem ?

Alexis.

PS: My TOS release number is 1.62, I have bought my STE 2 months ago.

I have posted an ST compatible patch to one of the newsgroups which
redid the DEFINE and also patched the volume name for Gulam! By the
way, where is Mtools 2.0 available for FTP?

P.S. PC's also have trouble with the single FAT: it depends upon
which application you use.

Over the years, reading newsgroups like this one, I have found that the best way to get a huge response from readers is to write something they can argue against.

Goal :- I want to know how operating systems (of the multitasking flavour) other than Unix perform I/O - how they implement device drivers..

Bait :- Unix has the best form of device I/O.
Unix device drivers are faster than all other operating systems.
Unix device drivers are the easiest to program.

If it makes you feel better, you can pretend I really mean it... flame me !!.

Please e-mail responses 'cos I may not read all the newsgroups I send this to.

959. Color Monitor Adjustments

Newsgroup: comp.sys.atari.st.tech
Date: 1991-01-02 14:16:32 UTC
From: ronw@cbnewsk.att.com
Message-ID: <1991Jan2.141632.7504@cbnewsk.att.com>
Source record: 49549

I came across a reference to Puget Sound Atari News article that
reportedly describes a proceedure to improve the color output of the
Atari color monitor. Is anyone familiar with this? I would like to find out more about it.
The article I was reading was talking about re-routing
a video lead in the 1040/520 to minimize digital noise pick-up that causes
faint vertical lines on the screen.

962. Questions for a TSR I'm writing

Newsgroup: comp.sys.atari.st.tech
Date: 1991-01-02 18:25:34 UTC
From: jlf@cs.wvu.wvnet.edu
Message-ID: <1175@h.cs.wvu.wvnet.edu>
Source record: 49552

Here's a few questions for the GEM gurus...

I'm writing a TSR that is going to use GEM and a resource that will
be compiled as part of the program. It is going to be activated by
exceptions.

Question 1...

Since I won't be using rsrc_load() to load the resource, how do I tell
GEM to initialize my resource. I've never used resources in this manner
before. Essentially, how do I use my resource? I'm using Laser C Ver 2.?
and RCP 3.0. I have created the resource and had RCP create the .C and .H
files for me. The only thing in the .C file is a large unsigned char array.

Question 2...

How do I calculate the number of bytes that the program requires to pass
to the Ptermres() function.

Last question...

I assume that even though this is going to be a TSR, I still need to
make a call to appl_init(). But what about appl_exit()? I have a feeling
that I'll never use this function.

Thanks in advance! :-)

963. MiNT and Neodesk 3

Newsgroup: comp.sys.atari.st.tech
Date: 1991-01-02 20:07:25 UTC
From: lunnon@qut.edu.au
Message-ID: <1991Jan2.150725.22196@qut.edu.au>
Source record: 49545

I have just received my Neodesk 3 upgrade and find that the new loading procedure for neodesk and MiNT do not get on :-(seeing these are my two fav. proggies I would like to see this fixed. I have isolated the problem to memory allocation. For some reason the mint malloc routine attaches all the system meory to the neodesk program or neoload and memory cannot be allocated to load the neodesk.exe bit. I suspect this is because neoload runs before mint and tries to load neodesk.exe (from a different copy of neoload) after mint :-(unfortunately I'm not a MiNT expert (Yet) but if no-one has a solution to this problem I am likely to become one ;-)

Ideas anyone

964. Running GEM programs from TOS/MiNT cli's

Newsgroup: comp.sys.atari.st.tech
Date: 1991-01-02 21:16:21 UTC
From: david@doe.utoronto.ca
Message-ID: <1991Jan2.211621.10795@doe.utoronto.ca>
Source record: 49554

I am writing a small program gem.ttp to run from bash, init, etc.
under MiNT. Ideally, I will be able to type

```
cd /dev/C/uniterm
gem uniterm.prg
```

in bash, and have uniterm crank up intact (or showdvi, or what have you).
The obvious way is to call appl_init(), open a virtual workstation, turn
on the mouse with v_show_c(0,0) (graf_mouse() doesn't seem to do the
job as well), clear the screen, turn off the text cursor (not in that
order), run the program, then turn off the mouse, clear the screen, turn
on the cursor, and return the program's exit code. Ideally, I should try
to lock the terminal first, and abort if I cannot.

The first problem is that the mouse seems not to work from a program
installed as TOS on the desktop. It will appear, but its clicks do not
register. Also, uniterm crashes no matter what I do. I would like to
be able to do this without GEM if I can -- just enable the mouse and turn
off the cursor. I can turn off the cursor, but what is the easiest way to
crank up the mouse? Help!

From: klute@tommy.informatik.uni-dortmund.de
Message-ID: <2898@laura.UUCP>
Source record: 49557

Thanks to everybody who replied to my recent Mtools question here.

Several people suggestest to define DUP_CAT in the file init.c. This worked fine.

However, the author of Mtools, Emmet P. Gray (fthood!egray@uxc.cso.uiuc.edu) brought to my attention, that the latest Mtools version 2.0.3. does not need the DUP_CAT definition anymore. This version also has bugs removed and new features.

Mr Gray said that he had posted Mtools v2.0 to the unix-pc.sources newsgroup (and mailed to the moderator of comp.sources.unix) on the 17th of September 1990. Since then, patches 1, 2, and 3 have been posted to unix-pc.sources, comp.sources.bugs, and emailed to Rich Salz. In addition, the current version of Mtools and all patches are available via anonymous ftp from cerl.cecer.army.mil (129.229.1.101).

I installed this Mtools version on my SPARCstation and I am working (i. e. interchanging floppies with my Atari ST) with it without problems.

968. two RSC files?

Newsgroup: comp.sys.atari.st.tech
Date: 1991-01-03 10:20:16 UTC
From: jeroen@ruuinf.cs.ruu.nl
Message-ID: <4593@ruuinf.cs.ruu.nl>
Source record: 49558

```
I am writing a program that uses a lot of dialogues.
The size of the RSC-file is approaching the 32000 byte-limit.
Can I split up the RSC-file in two parts?

I would write the following program:

rsrc_load(file1);
rsrc_gaddr(...forms from file1...);
rsrc_load(file2);
rsrc_gaddr(...forms from file2...);
...main program...
rsrc_free();
rsrc_free();

Is this possible?
Does the Atari keep track of the different areas of memory
to be released by subsequent rsrc_free() calls?

I would appreciate any help.
I will summarize replies made by email to the net.

Subject: GRAFX

Here is the small info about GRAFX I promised some time ago.
Could you please post this mail to comp.sys.atari.st and
comp.sys.atari.st.tech because I have no access to News here in Paris...

~~~~~~~~~~~~~~~~

Product GRAFX for Atari ST
Company PROCYON
65, Avenue Victor Hugo
F-33110 LE BOUSCAT
FRANCE
tel: +(33).56 50 54 10
^
this is the international code for France

Main Features :

PostScript interpretor; automatic or interactive mode
Display previewer
Text Editor included for the creation &/or modification of sources
Ability to use directly GDOS fonts or to convert them in PS compatible
fonts
external programs for customizing fonts

Files Included :

GDOS
GRAFX v1.1
PS fonts : Times-Roman, Times-Italic, Courier, Courier-Oblique,
Helvetica, Helvetica-Oblique, Olde
GDOS fonts : News, Lark
GEMFONT.TOS |
CVTFONT.TOS |
STDFONT.TOS |> customizing fonts
STDTOUCH.TOS |
Printer drivers : SLM804, quite all the dot printers

Other features :

export GEM-metafiles
ability to customize the pre-file CONFIG.PS

Everything is included in 2 disks 3'5; it is very easy to install it on HD.

Oops. Several people on the net should be able to mail you that one.

> and they don't include a place to which I could send money if I decide
> to use it. (I try to pay for shareware I use.)
>
> So the questions are:
>
> 1) Does anyone actually have the "other" distribution of 3.3c, with the
> files that are missing from the atari.archive files? --preferably
> source as well, but it won't ruin my life if the sources never show.

Sources are available from the MAST BBS, (612) 472-6582, in Minnesota,
which runs a Telebit T2500 -- you can snag the files at high speed using
either V.32 or PEP protocols. Use STadel to file-request "*.dir" from
the "STadel" room. MAST has source code to STadel and binaries for
STadel, Fortress, Citadel-86 and <fnord>adel. The sysop of MAST is
tacook@mast.moundst.mn.org; the BBS is a Citadel/UUCP gateway.

The problem with the sources is that they depend on the Alcyon compiler,
which almost nobody uses anymore, and Orc's personal mutant libc.a.

> 2) Does anyone have an address for David "orc" Parsons, so I can send
> him money if I decide to use it?

Orc's network address is akcs.orc@vpnet.chi.il.us or orc@jazz.sybase.com.
He has released STadel to the public domain and is (slowly) working on
a small, modular, portable replacement.

972. HD help

Newsgroup: comp.sys.atari.st.tech
Date: 1991-01-03 17:07:23 UTC
From: Bryan_Jones_Woodworth@cup.portal.com
Message-ID: <37527@cup.portal.com>
Source record: 49563

I am going to be getting a sizable tax return and would like to find out as much as possible about hard drive configurations. I find that from past experience, posting to usenet has been most effective.

I would like to know what would be the best way to go. SCSI w/the ICD host adaptor? What adaptor does Supra offer? What about RLL... what sort of interface/controller would I need for that? MFM? What are advantages/disadvantages to all of these?

How do I build a HD.. do I just need the HD, case (which sometimes includes the power supply, yes?), and host adaptor?

Help! A novice.

Bryan_Jones_Woodworth@cup.portal.com

973. Re: two RSC files?

Newsgroup: comp.sys.atari.st.tech
Date: 1991-01-03 18:13:31 UTC
From: kilian@seas.gwu.edu
Message-ID: <2492@sparko.gwu.edu>
Source record: 49564

Yes, there IS a way to use multiple resource files in an application.
Unfortunately, it involves a trick using undocumented GEM variables.
The technique was demonstrated in a German ST journal, but I don't
remember which one and when.

Apparently, GEM stores the root of the resource tree in an entry in
the global[] array, which can be found via the GEM parameter block
passed on an AES call. You should be able to use more than one resource
file if you do the following:

1. rsrc_load() the first file
2. rsrc_gaddr() all your pointers
3. save the global[] entry in a variable
4. repeat 1. and 2. for the second file

When your program is finished, you rsrc_free() the resources loaded
from the second file, restore the pointer saved in step 3, and repeat
the rsrc_free() call for the resources from the first file.

So. What is that entry in global[] that I've been talking about ?
Sorry, but I don't remember, and I can't check now because my ST is
5000 miles away from me at the moment. I suggest you look in some
recent book on GEM.

Hoping to have helped you.

>fan).

I moved up from a 1040 to a Mega ST2 and was annoyed by the the fan.
Then I bought a hard drive and was annoyed even more by noise of the
hard drive unit (yes it has a fan) and by the noise of the FaST drive's
fan. I always assumed I could cure the problem by drilling a hole in
the wall and then putting the hard drive on the other side |:^) .

>Opinions expressed are strictly my own.

Me too.

977. Blitter support chip info needed

Newsgroup: comp.sys.atari.st.tech
Date: 1991-01-04 09:26:29 UTC
From: jkenyon@janus.mtroyal.ab.ca
Message-ID: <1991Jan4.022630.4406@janus.mtroyal.ab.ca>
Source record: 49570

I'm own an Atari 2080ST (Yes, such a beast exists - even if it says marketing sample on the bottom :-)). Here's is the catch, I want to add a blitter to it (it has the socket) but I'm missing a support chip for the blitter. Any one out there know what it is ? If I add the blitter and boot the machine it hangs half way thru the booting processing before even getting to the hard drive. Remove the blitter and all is fine.

Techincal specs:

Board revision: C10059 REV 2.
The missing chip is a 20 pin DIP marked as U69 with it's associated capacitor marked as C98.
The blitter chip is marked as U66.
Both the blitter and the missing IC are near the lower right hand corner.
Most of the lines that run form the blitter to the IC are in the pins 50-60 roughly as numbered on the blitter.

Any help would be appreciated. Thanks.
Nick.

P.S. Atari doesn't officially support or recognize this model but any help form Atari personel would be appreciated. Allan?

978. Re: two RSC files?

Newsgroup: comp.sys.atari.st.tech
Date: 1991-01-04 09:58:34 UTC
From: fiebelko@maria.informatik.uni-dortmund.de
Message-ID: <9101040958.AA17860@maria.informatik.uni-dortmund.de>
Source record: 49567

Dear Jeroen,

> I am writing a program that uses a lot of dialogues.
> The size of the RSC-file is approaching the 32000 byte-limit.
You have a 64kB-limit (supported by Kuma-RCS 2.x & Digital RCS 2.x)

> Can I split up the RSC-file in two parts?
Yes, you can!

> I would write the following program:
> rsrc_load(file1);
> rsrc_gaddr(...forms from file1...);
> rsrc_load(file2);
> rsrc_gaddr(...forms from file2...);
> ...main program...
> rsrc_free();
> rsrc_free();
NEARLY right. Atari don't keep free the memory of the first resource-file.
You must save the address for the full resource tree from global[5,6].
This address points to the __first__ OBJECT of the loading resource file.
In most cases it's the IBOX for the menu-tree.

Two little routines, which will help you:
```
------------
void *rsrc_get (void)
{
extern int *global /* = _GemParBlk.global (for Turbo C) */ ;
OBJECT **rsc;

rsc = (OBJECT **) &(global[5]);
return (*rsc);
}

void rsrc_put (void *addr)
{
extern int *global /* = _GemParBlk.global (for Turbo C) */ ;
OBJECT **rsc;

rsc = (OBJECT **) &(global[5]);
*rsc = addr;
}

main()
{
void *save_resorce;
```

```
rsrc_load(file1);
rsrc_gaddr(...forms from file1...);
save_resorce = rsrc_get();
rsrc_load(file2);
rsrc_gaddr(...forms from file2...);
...main program...
rsrc_free();
rsrc_put(save_resorce);
rsrc_free();
}
------------
I hope it's right !!!! and would help you.

It does not cause an exception but simply crashes the ST. The problem
is due to the fact that setting the mouse vectors lasts more than one
cycle and thus may be interrupted. If the mouse moves while the vector
is beeing setted, the mouse handler is called and the ST crashes
because the vector is not a valid one. Try to write a program that
calls vex_motv 10000 times and move the mouse. With TOS 1.0, it
crashes.

>My STE definitively refuses to set its Date to any day
>after the 31 december 1999.

I just tried setting the date to 1/4/2001 on my TT and it works fine.
The code hasn't changed between 1.62 and this version, so I don't know
what to tell you. Try Tsetdate(0x2a24) -- the return code should be
zero, meaning it succeeded.

If you then try to print the date with a program which is not prepared
to handle the turn of the century, that can cause trouble, but it's not
TOS's fault.

Are you sure you're going to do this in a TSR? TSRs normally link into
some system vecors, i.e. TRAPs. The problem is: You can't call AES
from a TRAP handler. You will experience nothingbut crashes.
Would it be possible to do what you want in a DA? What kind of
function will the TSR perform?

Really? I've finished the program, and I've had no crashes (not even one
lockup). I do call the AES to throw up a dialog during an exception, but I've
had no ill effects (btw: I'm using (gasp) TOS 1.0)

> Would it be possible to do what you want in a DA? What kind of
> function will the TSR perform?

It's just a simple program which catches exceptions and puts up a dialog box
containing information about the exception and the CPU registers. Someone
put a program on atari.archive a couple of months ago to do this, but I was
unimpressed with it. So a couple of days ago I decided that the text messages
that Neodesk displayed on the screen were too crude (no offense, I _love_
Neodesk) for me - after all we're in a graphics environment, why not use it?

I'm putting the finishing touches on the program and writing the docs. As
soon as I put all of this together, I'm going to upload it to atari.archive.

Chris,
if you are really wanting to support SCSI devices, you ought to call
the ICD BBS (815)968-2229 and get the old versions of ICDHOST -- They
still support SASI. (whether or not the old versions work with the
Advantage, I do not know).

Laser 2.x provides a call to load the array as a resource and then it
can be accessed in the canonical way. I forget the exact name of the
call I think it's something like mrsc_load()... Read the release notes
that came on your original disks that's where it's documented. I have
code which uses this feature if you have problems later.

> from the command line.

Personal Pascal 2 has special subprograms (called CMD_ARGS and CMD_GETARG())
to perform this function. They were also available in Personal Pascal 1.

usage is describe on page 6-198 of the PP 2 manual and 6-94 of the PP 1
manual. Basically:

Cmd_Args is an integer function which returns the number of arguments in the
TOS command line buffer.

Cmd_GetArg(i, request) is a procedure which assigns the requested command line
argument to the argument ('request' is a string variable, 'i' is an integer.

As for Modula-2, it would depend upon WHICH Modula-2 compiler you were using
and the nature of the libraries included with the compiler.

I installed a blitter to my 1040 ST for a while ago.
To get it work, you have to unsolder two jumpers, marked with "W", located
near to the blitter's socket. (if I remember it correctly, above and left of
the blitter. These jumpers are similar to those used to select the size
of the TOS-ROMs)

These are Compressed files (don't laugh, that's what it's called!). From
the command line in Unix type:

uncompress *.Z

This will take all the .Z files and replace them with the uncompressed files.
You can get the COMPRESS.TTP utility from atari.archive in the archivers
directory. I have not used this on my ST, but I do have it. First time I
tried it on my ST I got 'not enough memory for this program' or something like
that...

The .tar files are something different altogether. you might want to do a man
page on tar (type: man tar) and you will see how to use it...I always forget
how to untar things and always have to look at the man page. It is not that
hard if I remember...maybe someone who does tar more than I can give you the
exact command (Howard?)

996. Spectre GCR & SCSI devices

Newsgroup: comp.sys.atari.st.tech
Date: 1991-01-07 14:16:08 UTC
From: gjh@hplb.hpl.hp.com
Message-ID: <GJH.91Jan7141608@ghiggins.hpl.hp.com>
Source record: 49586

According to the latest Gadgets Newsletter, the MegaTalk board offers a SCSI port which will allow SCSI devices other than HD's to be used under Spectre.

What's the position if I have an ICD-HostAdaptor-driven SCSI bus on my (non-Mega) ST? Can I hook a scanner on the SCSI bus and use it under Spectre (given the appropriate s/w)?

Thanks for any info.

Cheers,

Graham

998. MiNT 0.7 vs. TT

Newsgroup: comp.sys.atari.st.tech
Date: 1991-01-07 16:24:23 UTC
From: csbrod@informatik.uni-erlangen.de
Message-ID: <1991Jan7.162423.9488@informatik.uni-erlangen.de>
Source record: 49588

Can somebody help me out? I'm trying to install MiNT 0.7 on my TT/8.
It starts up, finds its INIT.PRG, but when I try to start up GEM
by typing 'gem', all I get is a bus error from an access to
$FFFFFC21 (used to be the real time clock in the ST, now there's
nothing to access). The crash happens inside TOS at $E1C24.
Since I learn from the MiNT README files that Allan Pratt did
the adaption to the TT and I know that he's listening, I dare
ask if somebody has similar problems or even a solution.

Judging from reactions on other nets here in Germany, other TT
users have the same problem.

Tnx in advance,

Claus Brod, Am Felsenkeller 2, Things. Take. Time.

From: ronw@cbnewsk.att.com
Message-ID: <1991Jan7.172828.26337@cbnewsk.att.com>
Source record: 49589

I'm trying to get information on where to obtain pieces for constructing
a hard drive system. Specifically, the ACSI<->SCSI converter and
disk controller.

ACSI <-> SCSI :
I know ICD, SUPRA, and Berkley Microsystems make these but the only
price/ordering info I have is from ICD. Can someone fill me in on the
other guys?

Controllers:
Where are good sources for the ADAPTEC 4000 and 4070 disk controllers?
Are there any others?

If there is enough interest, I could summarize for the net.

1001. KWEST Atari User Group - ST meeting - Wed Jan 9/91

Newsgroup: comp.sys.atari.st.tech
Date: 1991-01-07 19:49:28 UTC
From: daroloso@watmath.waterloo.edu
Message-ID: <1991Jan7.194928.17428@watmath.waterloo.edu>
Source record: 49391
Cross-posted to: uw.sys.atari,comp.sys.atari.8bit,comp.sys.atari.st,comp.sys.atari.st.tech

The Kitchener-Waterloo Eight Sixteen Thirty-two (KWEST) Atari user group,
has a separate 8-bit meeting and 16-bit meeting.
We meet monthly, have special interest groups (SIGs), associated bulletin
boards, public domain libraries, and a newsletter "The Hard Copy".

I am on the executive of the group
so I should be able to handle most questions or
get replies from the rest of executive.

The group welcomes new members and visitors with
8-bits, 16-bits, or those just curious.

Meetings held at the University of Waterloo in the
Math & Computer Building.

Rooms open at 7:00 pm. Meetings start at 7:30 pm.

Call 579-3695 for details.

Next Meetings
****

16-bit (ST) - Wednesday, Jan 9, 1991
DCS Course Room, Room 2009 (2nd floor)

Hope to see you there,
Dani Roloson

1002. Moving a hard disk

Newsgroup: comp.sys.atari.st.tech
Date: 1991-01-07 21:27:16 UTC
From: petcher@wuphys.wustl.edu
Message-ID: <1991Jan7.212716.16403@wuphys.wustl.edu>
Source record: 49395

I just made a move from Florida to the Midwest, USA (Yup I know it is the wrong direction to go this time of year - my new neighbors wonder what kind of crazy guy I am) and my hard disk seems to have arrived in less than satisfactory condition. It boots up OK, but sometimes some files are not recognized (including a whole partition that is sometimes missing) althouh at other times they are there. I also get a number of read failures, but the strangest thing is that whenever I execute a program, when I quit from the program the computer just hangs. This only occurs when the hard disk is hooked up. From floppy everything looks fine (as far as I can tel so far). Any clues? I have a Berkeley Microsystems BMS200 board hooked up to an Adaptec 4070 and a Seagate 4144R drive.

Yes, you get a bus error when you try to fire up the Desktop under MiNT.
I don't know why. I never do this, so I didn't analyze it. If somebody
figures this out, send mail to Eric Smith, not me -- it's his baby.

Source record: 49393

> hardware in general. It seems to me that I can just pull out my old
> 68000, plop in a new one rated at 16MHz, and then run the 16MHz clock
> line to the new 68000? For that matter, can I move up to a 68020

Chris,
This is a no go, because of the way that the CPU and the MMU swap cycles. From what I understand, the system clock ALREADY runs at 16 Mhz, but it gives half to the 68000, and half to the MMU. (I may have the wrong chip...it may be the glue...)
Anyway, since THAT chip, and all the support chips are not rated at anything like 16 Mhz, and all the timing is sensitive, you try to double the speed of the system clock, and you have an expensive paperweight.
I think the speed up kits available use a caching technique, so that the new chip DOES run at 16 Mhz, for it's cache, and 8Mhz for anything else. That way, you do get the speed improvement, and the system timing doesn't change. Only problem, is that that usually requires a caching chip, and another daughterboard, making the cost more than $100.

If I'm wrong here, please jump in, I'd LOVE to be able to speed up my ST for <$100....(grin)

1005. Error P at FACCC2

Source record: 49397
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

I have just started to get an error when starting up certain
programs, specifically the Prospero Fortran workbech and associated
utilities....it says

Error P at FACCC2

when I click on the program icon (from Neodesk or not).
The executable is on my hard drive but I get the same error when I try
to run from floppy , only the error address is changed to

F9FC04.

My question is where is this address??? Is this a RAM error??? And if so,
why do all my other programs work (Uniterm, Tempus...).
Or is the address in the ROM?? I don't know where they are mapped. If it is
in the ROMS, could it be do to changing over to TOS1.4?? I don't remember if
I have tried this since I did the change.

Anyway, does anyone have any suggestions?

thanx,
james

1006. Setting a 2000 year date *HELP*

Newsgroup: comp.sys.atari.st.tech
Date: 1991-01-08 12:06:27 UTC
From: alex@hpgnd.grenoble.hp.com
Message-ID: <17750004@hpgnd.grenoble.hp.com>
Source record: 49394

Hello,

In a previous posting, I was saying that my 520STE with TOS 1.62 keep
refusing a date afer 31 december 1999.

Alan Pratt has answered :

>I just tried setting the date to 1/4/2001 on my TT and it works fine.
>The code hasn't changed between 1.62 and this version, so I don't know
>what to tell you. Try Tsetdate(0x2a24) -- the return code should be
>zero, meaning it succeeded.
>
>If you then try to print the date with a program which is not prepared
>to handle the turn of the century, that can cause trouble, but it's not
>TOS's fault.

So I made two little programs : TGETDATE.TOS and TSETDATE.TOS to
try this on my 520 STE. You will find the sources hereafter.

TSETDATE.TOS calls Tsetdate GEMDOS with 0x2a24 parameter to set the date
to the 1/4/2001 , and prints the return code of Tsetdate.

TGETDATE.TOS prints the long integer return code of Tgetdate().

The results are:
Tsetdate.tos : prints that tsetdate returned 0 that means that everything
went well.

Then I call Tgetdate.tos and it prints the system date that was BEFORE
the call to Tsetdate...

I also experienced this phenomena with the BIOS call Gettime() and
Settime();

So anyone has an idea ?... What's happenning ? May be the French version
of TOS 1.62 has some new bugs ?

Thank very much for helping me .

Alexis MERMET-GRANDFILLES.

```
>>>>>>>>> ------------ Tgetdate.c -------------<<<<<<<<<<<<<<<<<
#include <osbind.h>

main()
{
printf("Tgetdate returned 0x%x\n",Tgetdate());
gemdos(0x1);
}
```

```
>>>>>>>>>>------- Tsetdate.c -----------<<<<<<<<<<<<<<<<<<<<<<<<<<<<
#include <osbind.h>

main()
{
printf("Tsetdate (0x2a24) returned 0x%lx\n",Tsetdate(0x2a24));
gemdos(0x1);
}
```

1007. Programming help wanted..

I hope someone out there can help. Here's what I'm trying to
do.
- write a program that will run and then call another program
from the same .PRG file.

E.g program file WORK.PRG will in fact be two programs
CHECK.PRG and THIS.PRG

CHECK.PRG will execute first and then call THIS.PRG.

I also want to able to remove CHECK.PRG from THIS.PRG and
seperate the two again.
I know it can be done because I've got several compacter programs
that do it (run the decompacter and then run the program) but I wish to
do it.
The reason why I want to do this is to create some sort of
access control for the shell I am writing.
My language of choice is GFA BASIC 3 because thats what all
the development is being written in. C(Mark Williams) is acceptable though.

P.S I'm using a 520(1meg) STe with tos 1.6

Thanks a lot in advance.

I once bought a used hard drive that had to be shipped across the country.
It too had intermittent problems. About the same time, a friend
of mine starting having similar problems. We were both about to send the
things to the factory for repair, when we decided to try looking
at the internal connectors. After disconnecting the power, I opened
the box I disconnected the various cables, looked at them, scratched
my head, put them back together, "jiggled" them a little bit, and
then closed the box and re-connected the power.

I then re-booted the system and things worked! Everything has worked
fine on both drives since. We both feel very lucky.

I can't say that I recommend that you do what I did, but if you feel
like trying, you might have the same luck I did, and save your self
the bother of calling in a technician.

The cheapest speed-up board I've seen was a project by the German magazine
"c't" (one of the fall issues, but I can't check it now). It should be around
$100 or cheaper, IF you're prepared to put it together yourself.
As far as I remember, it only speeds up accesses to the ROMs and internal
CPU operations, in RAM it runs at the normal speed (you can't speed up RAM
accesses because the Shifter needs to access video RAM at fixed intervals).
It has no cache, so it isn't as effective as the commercial boards, but it's
CHEAP.

1011. Memory upgrade problems brand new ST/STE

Newsgroup: comp.sys.atari.st.tech
Date: 1991-01-09 01:16:41 UTC
From: jkr@ifi.uio.no
Message-ID: <CMM.0.88.663383801.jkr@skakke.ifi.uio.no>
Source record: 49400

Ok, here's a couple of unusual RAM upgrade problems...

The first one's a brand new STE,- this is the absolutely latest
model. I work part-time in a computer shop and these came in just
about one month ago. (Paint still fresh).
The machines work fine with 2 SIMM modules inserted. Insert 4
modules (of any type) and there are several different reactions.
Upon booting the STE language disk the "POOL FIX INSTALLED" appears
onscreen. Then after 0.5 second EVERY SECOND character fades out. A similar
effect may sometimes be observed on the Desktop. About 50% of all software
works while the extra 2 modules are inserted. It may seem to me
like the CPU recognizes the RAM but that the VIDEO CHIP has
problems with it. This is only a guess, I haven't been in there
with a machine code monitor to check. I've tried shielding the modules
from the switchmode power supply, but it doesn't seem to help. I've
compared the Motherboard with a previous release STE that handles the SIMMs
properly, and I have found no (obvious) differences. Resistors R405 & R459
(Behind SIMM sockets) are missing on both versions of the board.
Anyone have any suggestions ?

The second one's more conventional:
A 520STFM, again the latest model. Just to be on the safe side I
soldered in SOCKETS instead of soldering the RAM straight in.
I have not installed the condensators, JUST the sockets. The
problem is that the machine doesn't work. I get various amounts
of bombs,- the interesting part is that in the black part of the
bombs I get random 'sprinkles' of colored pixels that come & go.
(Kinda like multi-colored "snow" from the old IBMs)
(They seem to be generated by the video circuitry because the do
not remain on screen)
Due to the width of my sockets I had to solder 4 of
the RAM chips directy onto the motherboard (this has always worked fine
earlier..) The symptoms are much the same regardless of whether the 12
remaining chips are
installed or not. I have a feeling this problem is noise-related,
although that may only be a part of the problem. I do not think
this lies in the custom chip sockets, although there's always a
possibility...

i just checked out an ST version of unix date(1) i wrote. it correctly
sets the date on a mega4 (tos 1.2). however, i needed to do 2 things:

1) call GEMDOS Tsettime/Tsetdate to tell GEMDOS of the change
2) call XBIOS Settime/Setdate to tell the ikbd of the change
(Tset* does NOT do this).

you need to do both as far as i can tell. at any rate, it does not seem
to hurt. maybe apratt can elucidate...

try that. if u insist, i can mail u the src for this program...

The First Word Plus looping keyboard problem struck me again this week.

To recap, this is different to the Phantom Typist, where events seem to
get delayed, but you can usually do enough to save your work and reset.
1WP is more usually afflicted by a problem where in the middle of typing
it repeats your last few characters several times and then bombs.

Way back last February...

grahamt@syma.sussex.ac.uk (Graham Thomas) wrote:

> GST say it's something inside TOS (or GEMDOS or whatever layer

If you don't like the look of gore, please turn away :-) The following is
the output from the utterly brilliant SYS_MON of the central loop in 1WP,
with comments by me based on a little extra detective work with a low level
debugger. It makes interesting reading, but as to whether the way 1WP works
causes this problem...

My copy of 1WP is version 3.14. The problem occurs in all ST versions of
TOS.

1016. Alignment problems with Pexec()

Newsgroup: comp.sys.atari.st.tech
Date: 1991-01-09 18:44:42 UTC
From: kilian@seas.gwu.edu
Message-ID: <2511@sparko.gwu.edu>
Source record: 49410

While implementing a Prolog system on the ST, I came across the following problem:

I'd like the program to be able to pre-load the Prolog code of the compiler and library and to 'dump' itself to a new executable file. When starting the new file, the Prolog code will be present in memory, greatly speeding up the startup process. [For those not familiar with such a technique, this is exactly what GNU Emacs does, at least on a UNIX system].
On the ST, this is a bit complicated since programs can't assume that they will always be loaded to the same address (I already figured out how to generate relocation information for the new executable file, so that's not my problem). In particular (as I understand it), TOS only guarantees that a program will be loaded on an EVEN address.
THAT'S my problem.
In the program I'm writing, the least significant 2-3 bits of a pointer are used as type tags. To make this work with the relocation scheme implemented by the TOS function Pexec(), the dumped executable program must be loaded to an address that is congruent (modulo 8) to the original load address (speaking C: (old_adress - new_address) % 8 == 0), which simply can't be done under the normal TOS.

Does anybody know a solution for this problem ? It is not simply a matter of putting a program in the AUTO folder that intercepts all Malloc() requests and forces 8-byte alignment, since Pexec() predictably doesn't call Malloc() (it calls some internal TOS routine which can't be trapped). I don't feel like rewriting Pexec() either. The program is intended for public use, so fixing the ROMS or using a modified RAM TOS won't help.

[In case someone is interested in the program, a pre-release version is available from comp.binaries.atari.st]

Thanks for any comments

Jens Kilian

> The first one's a brand new STE,- this is the absolutely latest

> The machines work fine with 2 SIMM modules inserted. Insert 4
> modules (of any type) and there are several different reactions.

For testing at least, use four of the *same type* - do not mix 256K
simms with 1Meg simms, the STe will get very confused otherwise.

> Upon booting the STE language disk the "POOL FIX INSTALLED" appears

> compared the Motherboard with a previous release STE that handles the SIMMs

I can't really help on this one, the missing resistors may well be the
problem. On regular STs memory problems can run from missing
resistors and capacitors to a bad MMU. Certainly the strange screen
problems are due to bad high ram. Speculating wildly, it might even
be only 1 bank of the high memory ram.

> properly, and I have found no (obvious) differences. Resistors R405 & R459

> I have not installed the condensators, JUST the sockets.

And so's the answer 8-). PUT IN THOSE CAPS! They are what kill the
switching noise from the RAM. You should also check for a bad MMU,
and for all the necessary resistors and caps for the second bank,
Atari doesn't always put them in.

> The problem is that the machine doesn't work. I get various amounts

1018. Question, RE: ICD host adaptor & Conner Data HD

Newsgroup: comp.sys.atari.st.tech
Date: 1991-01-10 01:34:39 UTC
From: Bryan_Jones_Woodworth@cup.portal.com
Message-ID: <37793@cup.portal.com>
Source record: 49405

I have a question. I will be buying a 90 meg 18ms CDC (Conner Data Communications??) hard disk drive. Will this be supported by the ICD host adaptor with the clock? I ask this because of the following text I read:

>I own two ICD Host Adapters. If you plan on buying a new ICD Advantage
>Host Adapter, TRASH THE SOFTWARE! The programs are really poor. They
>don't support SASI devices anymore, and you can't enter your own HD data
>for off-brand drive mechs. I use the Supra software with my Advantage
>ST.

Was wondering, is the Conner an "off-brand" drive mech?? Whatever, anyway as you can see I am a novice and need.. HELP!!!

Email is fine if you are the shy type.

thanks,

Bryan_Jones_Woodworth@cup.portal.com

1019. MGR books

Newsgroup: comp.sys.atari.st.tech

I just downloaded MGR for the ST about two weeks ago and I'm really
impressed (speed is of course a problem; any body using it with
any of the ST accelerators?). I'd like to start moving some of
my programs to MGR. Does any know of any books about MGR ? Anyone
have any? Anyone interested in trading some such beasties for some
X-windows programming books?
.

HELP!

I just got a copy of STadel from terminator...(3.3a, I believe)...and it does a creditable job as a BBS. I'm now wanting to use it as a UUCP node. Anybody have any advice or horror stories about setting such a situation up? From the docs, I can see what is supposed to go on on this end, but what about the other end? Should I try to talk to the University I attend, or is there any feed to Usenet through local computers in the Dallas area? Thanks for any information.

Some people like to think that there machines will last forever, there
are some funny things with the Date Commands, that is why there are a
lot of Date setting programs, by the way you seem to be of the same
opinion, will Unix last that long, I thought it was allready dead !!
by the way I vote for ZIP, :-)

Here is a question for all you TT owners out there:-

If drag some files from a window on drive A to drive B does the desktop
store as many files as it can in memory before writing them to drive B
or does it prompt for a disk swap between each file? I would consider
swapping disks between each file to be a major cockup.

From: jamie@defoe.enet.dec.com
Message-ID: <18805@shlump.nac.dec.com>
Source record: 49413

Hello!

I wonder if anyone has a listing of 68000 instruction timings for the ST
? I've got a couple of books on ST internals and 68000 programming but
neither of them mention instruction speeds at all. I'm trying to write
some code to remove all the borders so I need to know exactly how many
clock cycles each instruction takes in my code...

Can anyone help ?

Cheers,

Jamie.

This is the only practical way to avoid this problem properly. I do
the same in an editor routine of mine. I _know_ that it is not OK
to do this as you are struggling with AES and XBIOS keyboard routines
at the same time, but there seems to be no better way, and it
works with all available TOS versions.

If someone out there (maybe @atari) knows some better way to handle
this, please let me know. We are not satisfied with this solution,
but it's the best we could find so far.

Apart from that, I really think the phantom typist is a TOS bug.
It occurs in many programs, not only in WPLUS. Some friend of
mine told me at the last Atari fair in Duesseldorf that he
thought he had found the reason for it, and that it lies in
an internal TOS routine that is responsible for some keyboard
functions. It is not only called as a normal subroutine but also
from an interrupt, and it is not properly guarded to avoid
problems when the interrupt occurs while the main program is
in this routine at the same moment. A description of this has
been sent to Atari US (to Ken Badertscher, to be exact), as
I have been told. So maybe Ken knows more about it now and can
shed some light on it?

Sure. Get the Motorola MC68000 Microprocessor User's Manual,
published by Motorola, Inc. The instruction timings take up 8 pages
of an appendix (in the version of the manual that I have)! They are
quite complicated and depend on the particular instruction, addressing
mode and lengths of the two operands.

I'm going to be mealy mouthed here, as I have been too often incorrect
in my answers recently. 8-) The Contol Data Corp (owned by Seagate
now?) drive will probably be fine, it's just that ICD no longer does a
complete low level reformat on embedded SCSI drives. I have read in
comp.sys.amiga.hardware that some drives don't even allow one, and
have to be returned to the factory if they need it. Even if I'm
wrong about the low level format, it is true that the ICD software no
longer uses its own database of drive characteristics for SCSI drives,
instead it queries the embedded drive, and uses that info for the
formatting that it does. The information is written by the drive's
manufacturer on some "hidden" (negative nos?) sectors of the drive, if
it's blown away, you're SOL - until you get a more DIY type of
formatter. ICD does have one for their earlier (3.XX) driver
software.

good luck,

I have been trying to get my original PC-Ditto software emulator working. Since Avant-Garde is out of business, can someone help me?

I have an ICD host adaptor, Quantum 80MB SCSI drive, and a standard Mega 2 ST. I am using IBM PC-DOS version 3.30 and PC-Ditto version 3.00. TOS 1.4 is installed.

I have gotten PC-Ditto to run, it recognizes 4 partitions on the hard drive (from the initial screen), I insert a DOS 3.30 floppy, which successfully boots and I am faced by an A> prompt. HOWEVER, when I attempt to FORMAT C: /S as requested it gives a divide by zero error. When I do an FDISK I get another divide by zero error. Help me!

I have cleared out the C: partition (0) on my hard disk and would like to install DOS on there. I have removed everything from this first partition and in the meantime I am unable to use my hard drive. Does anyone know what the "divide by zero" error message is coming from?

Blitzkrieg ('tanks in advance),
Chris

>When I do an FDISK I get another divide by zero error. Help me!
>[...]

Formatting your hard drive was major overkill. You don't need to
do that to install DOS on it.

Just type "SYS C:" and that will copy all the system files. I think
that should be enough to get you booted. I think SYS also modifies the
boot sector so that DOS can boot off of it. Either way, once you've done
that you could just copy your DOS files to drive C: (you could even do the
copying from the desktop if you wanted) and that's all it takes.

Formatting your hard drive is a lot to sacrifice to get DOS on
the hard drive. Heck, just having DOS take up the space is a waste! :-)

I don't know about the rest of your problems. Wish I could help.
Good luck.

Source record: 49419

Hello,

Please send flames to /dev/null.

Some people has been using apple for near 10 years. Why ST or TT machines
should not still be appreciated as home computers in 9 years.

Back to our problem:
---

1)

TOS 1.6 has corrected a early TOS bug that was :
Any change to the GEMDOS clock was not forwarded to the keyboard internal
clock.

This now works on my TOS 1.62 . If I call a (GEMDOS) TSetTime() , I can
retreive the value I put by calling a (BIOS) gettime().

2)

But my problem is different. Everythings works well if the date is before 2000.
If I try to set a date after the 2000 year , the GEMDOS seems to accept
the request , then it tries to forward it to the keyboard clock which seems
to refuse it. Then the GEMDOS clock is set back to the previous value it had.

Actually, If a program sets a 2000 year date with Tsettime() ,then gets the
date with a Tgettime() call, the Tgettime() returns the correct 2000 year date!

But then, if you quits it, return to the desktop
and run a little program that read the date, you get the previous value ???

Strange isn't it.

Atari users, is it reproducable on your systems ? on the TT ?

I am wondering if this may be a side effect of any French adaptation of the
TOS.

Alexis MERMET.

1030. Monitor and floppy plug/socket source

Hi!

In case anyone's looking for connectors for floppies (14-pin din) and/or
monitors (13-pin din) then you can get them at Maplin's (I just found out),
and they seem pretty cheap:

code:
JW95D 13-pin din plug 98p
JW99H 13-pin din skt (pcb) 128p
JW97F 13-pin din skt (inline) 128p

JW96E 14-pin din plug 120p
JX00A 14-pin din skt (pcb) 128p
JW98G 14-pin din skt (inline) 148p

-If you haven't got a local shop (or live outside the UK), they're on

0702 552911 (PO Box 3, Rayleigh, Essex SS6 8LR)

(Not connected with Maplin's in any way of course, just been looking for a
cheap source for sooo long and though it might be useful to others...)

>>some code to remove all the borders so I need to know exactly how many
>>clock cycles each instruction takes in my code...

Be sure to include in your calculations that, on the ST, some instructions
may take longer than what Motorola tells you. This is due to the fact
that there are some 6-cycle instructions, and the ST bus is shared between
processor and shifter on a 4-cycle-basis. Thus, these instructions can
effectively take 8 cycles instead of 6!

(This applies to any instruction which has an instruction time which
is not a multiple of 4.)

Why not just take out the 68000 and put in a 68010, most software should run
and should run about 10% faster.
People do this to thier amigas,but they have a piece of pd software that gets
over some minor incompatability problems.
P.S. Its a very cheap upgrade too.
Not sure if this will work but it should

I have the same problem with PC-ditto on my ICD hard disk drive. I first thought it was due to having a C: partition too small. I've increased it to 6Mb and I still get the divide error whenever I try and access it (and this includes trying to SYS C:).

No Go. I desoldered my 68K and put in the 68010. Turn it on, the screen clears, everything looks great! The drive light comes on...

Then, bombs, the screen clears, and more bombs! It keeps bombing till you turn it off!

I looked through ST Internals and found some MOVE SR type instructions, in the boot-up sequence, which are privileged on the '010, and not on the '000.

Now, I want to know if its my silly TOS version, that is, 1.0, which causes this problem, and if it's been fixed for TOS 1.2 or 1.4.

Theoretically, TOS 1.6 should run....

I have some patches that I never implemented. Perhaps I'll get the time oneday....

From: tkld@cs.ed.ac.uk
Message-ID: <4454@skye.cs.ed.ac.uk>
Source record: 49428

What is the "right way" to read the state of the joysticks, and return
everything to normal after I've finished ?

Do I just hook a routine into joyvec to receive stuff from the keyboard 6301?
Should I tell the 6301 to send joystick messages instead of mouse messages ?
How do I reset it (should I check what it was first with a status message)?

Suppose I want players 3&4 on the centronics port too, do I poll or can I use
interrupts ?

Anyone got code to do it ? I started, but got fed up rebooting if I
screwed the mouse vector.

I'm sure loads of peeps would love to know how it's "supposed" to be done.

The Jan/Feb issue of Atari Explorer says TT TOS includes an exception-handler
in the BIOS that traps this error and replaces it with a move from CCR.
Apparently TOS ROMs are not the only software with this instruction.

(I don't know whether TOS 1.4 and 1.6 have this error-handling, or whether
they include the offending instruction.)

Hello,
I am trying to write a shell program (due to the idiosyncracies of gulam), and I have made several attempts to do input/output redirection with varying degrees of success. Please could someone out there tell me the 'proper' way to redirect IO before a pexec call (thinking in terms of a shell program). Do you have to preload the program, do the redirection, and then re-pexec, etc.

Please mail me any solutions, I will summarise to the net if necessary.
Thanks,
Andrew

1044. Problems/Questions about Chinon HD drives.

Newsgroup: comp.sys.atari.st.tech
Date: 1991-01-14 21:58:43 UTC
From: adamd@rhi.hi.is
Message-ID: <2623@krafla.rhi.hi.is>
Source record: 49437

I have twin Chinon FX357 drives connected up to my 1040STF with TOS 1.2
Both drives are on the same flatcable and they are configured as drives
0 and 1 by setting the jumpers. The flatcable is not twisted (which would
exchange DS0/DS1 for two DS0 drives) so the setup should work perfectly, but
drive A: (slightly further away on the flatcable) only just works when cold, and
refuses to read correct data from disks when warm unless the other drive is
disconnected. Each drive works perfectly well in isolation from the other.
It is enough to remove the power from drive B: to restore full working order
to drive A: , even when running hot. What is going on here? Do I have to
terminate the drive chain (there is 2.5 cm of flatcable between the drives,
less than 25 cm of flatcable between drive B: and the drive connector on the ST,
and Spectre GCR injects into the 14-pin DIN connector)? Everything works just
fine (including Macintosh disks) except after the first few minutes when both
drives are connected. The drives are 5-Volt only types so they could be putting
too much of a strain on the power supply I suppose. What is the expected power
consumption of Hypercache + one extra drive?
(BTW these are "intelligent" drives that only spin when a disk is in them).

Can anyone help with these problems?

It's a pity that these drives have caused problems with installation, and that
other people have had various problems with these drives, because there is no
other 3.5" floppy drive as robust & reliable as these Chinons once the possible
difficulties of installation are over.

Now for the questions:

(1)

I caught the tail end of the "Media change problem" thread a while back.
Did anyone find a way of fixing these drives (or fixing TOS) in order to solve
this one? The problem as I see it is as follows:
The drive as shipped (and connected by all 34 pins to the ST) does not recognise
a disk change event unless the disk is write protected. "Normal" Atari drives
under Spectre flag a disk change if the disk is write enabled, but not when the
write-tab is open. Here's where it gets really weird ...
Spectre will automatically register a disk change on write-protected disks on
these drives and ignores write-enabled disks that get changed, whereas normally
it is the other way round. However, the GEM desktop will always cause a disk
access and update on both types of drive if the disks write-protected, whether
the disk has been changed or not. The only workaround without modifications is
to insert a write protected disk in the drive after removing / before inserting
a write-enabled one, but that makes Spectre think the disk has been changed
twice :-(
I most definitely do not wish to lose the capability of these drives to notify
Spectre of write-protect disk changes. Therefore it is not an acceptable

solution to hardwire the switch contacts in order to emulate the "normal" Atari drives. I am seeking a solution whereby both write-protect conditions will trigger a media-change event when a disk is changed. I imagine that a suitable pulse generated by the media-change signals and drive-select signals could be combined with the write-protect signal by some trivial logic to produce a modified write-protect signal that would fix these drives - maybe even fool Spectre to recognise any disk change once only. 8{:-)}
(BTW Epson and Citizen drives suffer also from the same problem). I guess that the drive-select signals are pulsed in turn and the write-protect line sampled, in order to decide which drive has "glitched" the line. Am I missing anything here? It sure makes better sense to make the same change (in hardware or software) for all the drive types, than to fix each different make of drive with a bodge that only works on that particular type.

(2)

Please can some kind soul tell me what pins 1,3,5,7,9 are used for on the Chinon FX357 drives? I read that a certain amount of non-standardness exists here between some of the manufacturers.

(3)

Can someone point me towards reliable DIY methods of getting the full speed and density out of these HD drives? Has anyone already written a PD formatter and/or driver for these beasts?

Thanks for reading, and any help welcomed!

Adam David. adamd@rhi.hi.is

I assure you it has nothing to do with being in France. The countries that we do ROMs for get their ROMs from headquarters, and there are no differences in low-level time handling.

I have just done some research on the clock handling, and I think you're right: if you don't have a clock chip in your system (i.e. not a Mega ST or Mega STe or TT) then the keyboard clock is regarded as the most correct one, and it uses the "last two digits of the year" method of keeping time. This is too bad. If you have a clock chip, either the kind in the Mega ST and Mega STe (from Ricoh) or the kind in the TT (from Motorola), then your IKBD clock is never used, and this problem does not arise. Also, of course, if you have some third-party clock chip and a TSR that intercepts the Xbios Settime/Gettime calls, you won't have this problem.

Sorry I blew you off earlier: I forgot that there was so much variation in timekeeping in the Atari computer line.

It is certainly possible to fix this in the BIOS or with a TSR, but I don't think it'll be a priority for 9 years or so :-)

I think a lot of tos programs probably use Conin() to wait for input
and this would effectivly stop any background process that was Gem-based
from running. I think shadow works from the serial interupt, and therefor
can over-ride anything that doesn't set the IPL higher.

Here's the deal: The ST basically has a single-tasking operating system. When a program is running, it has total control of the computer.

GEM adds a gross and clumsy sort of multitasking capability. A GEM program is ``event-driven'' -- it usually knows how to respond to any of many possible events, such as a keystroke, a drop-down menu selection, etc. To accomplish this, a GEM application tells the operating system what event(s) it may be interested in, and hands control to GEM.

Multitasking comes into play when GEM (actually the GEM AES Event Manager) has control of the system. It can dispatch event signals to more than one application. By cooperating, desk accessories can work in conjunction with primary applications. The DAs and the main program simply go to sleep (by calling the Event Manager) and wait for a ``wake-up call'' from GEM.

In addition to physical events like a keystroke, an application can wait for a ``timer event''. This makes it easy to write a desk accessory that performs uploading and downloading in the background. The DA calls the Event Manager frequently, letting it parcel out bits of time to other applications. When it is activated, the DA checks the ST's serial buffers and processes any data that is queued up.

But .TOS and .TTP applications such as Gulam, MicroEMACS, compilers, etc., aren't GEM applications, and they never hand control over to the Event Manager. They never ``go to sleep.'' If they want a keystroke, they don't bother with the Event Manager. Instead, they issue a direct call to the operating system that blocks other activity until it's satisfied. Therefore a DA such as STalker never has a chance to ``wake up'' and

process background data.

Fortunately, GEM isn't the only way to ``multitask'' under TOS. Another way is to take advantage of the ST's ``VBI queue,'' a list of routines that are executed every time the video display is redrawn -- about 60-70 times per second, depending on the monitor. VBI stands for Vertical Blank Interrupt.

VBI routines are a little harder to write, which is why you don't see many of them, but they work the same way: They're ``awakened'' repeatedly and they have to do a little bit of work, then voluntarily ``go to sleep'' so the system can proceed. There are programs that perform background file transfers, spool printer output, etc., using the vertical blank interrupt, and they will work happily in conjunction with a non-GEM application.

GEM is multi-tasking (not in the unix way), TOS is not. As GEM does
not have a scheduler which is interrupt driven it relies on calls
to dispatch other processes. This gives the appearance of background
running where in effect the background tasks are only run when the
main application has made a GEM call (to get a char, update the screen etc)
A shell uses only TOS calls so this cannot happen - hence no background
tasks.

However having said that, I notice that Mupfel occasionally allows my
background clock to run.

I do have a Manual called Programmmer's Reference Manual
M68000UM/AD , Prentice-Hall, ISBN 0-13-541491-1, there is also a Pocket
book version of this manual used to come with the HighSoft DevpacST
also I have a Programming card, MC68000(AC1), all this was from the
Motorola agent here in Wellington NZ,, ..VSI..

1051. Re: Problems/Questions about Chinon HD drives.

Newsgroup: comp.sys.atari.st.tech
Date: 1991-01-15 15:15:17 UTC
From: adamd@rhi.hi.is
Message-ID: <2626@krafla.rhi.hi.is>
Source record: 49452

I've narrowed down the possible causes for the problems I encountered with
dual Chinon FX357 drives.

Basically:
1) it is not related to the power supply,
2) it is not caused by heat,
(only worsened by it, there are only two states: Drive A: functions correctly
or drive A: consistently reads the same garbage. I have not dared attempt to
write data to drive A: while the drive is malfunctioning),
3) the floppy controller is in good order,
4) it does not appear to be caused by Spectre GCR (though possibly accentuated),
5) I doubt if signal termination is a problem. The dual drive setup works 100%
if one or both of the drives are standard DD types. Therefore:
6) I strongly suspect that the problem is signal interference between the two
drives on one of the five pins that used to be earthed on the older types.
What do these signals do?

I can probably "fix" this by simply cutting a few wires in the cable, but I am
not happy with applying a blind fix. See my previous posting for why not.

Thanks for any help,

Nope, won't work. As I understand it, the stackframe size is
different and corners were cut in TOS. The line F stuff may interfere
with things too - don' t know enough about '010's to tell. In general,
if you want to run a 680X0 where X>0, you need a fixed version of TOS,
either a german patched eprom version or TOS 1.62 from Atari. Also,
remember that the 68000s are soldered into Atari STs.

1053. 49 line sto a screen

Newsgroup: comp.sys.atari.st.tech
Date: 1991-01-15 18:00:15 UTC
From: fields@triton.cray.com
Message-ID: <115744.2326@timbuk.cray.com>
Source record: 49453

Does anybody know how to switch the screen into 49 line mode
such that the VT52 emulator software works as if it WAS 49 lines ?

I used to be able to do it with the routine :-

```
FONTSMALL: LEA.L $FD2CA6, A0
JSR $FC4A98

RTS
```

And doing a JSR FONTSMALL.

A similar one, FONTBIG, set the screen back.

This used to work, I don't know, but I presume it was under TOS
1.0 and now I have 1.2 (and 1.6) and it doesn't work.

It sure would be nice to get back to having 49 lines (Beckemeyer
CSH works with 49 lines along with various editors.

My internal floppy drive gave out on my 1040 the other day. I went to a store and asked for a 720K drive, but they gave me a Teak drive and said it would work as both 720 or HD. Reluctantly I took it, but I know on the phone they said they had 720K drives made my Mitsubishi (sp?). The Teak drive did not work, no matter how I tried to position the jumpers. Will those drives just not work, and do I need to get just a 720K drive?

I have an STe and I wanted to try this too.
The STe has a square package 68000, and all I have is a rectangular 68010.
I have toyed with the idea of making an "adaptor" or actually getting the
68010 in the right shape, but I don't really want to put any/much money
into this.

Well, I'm hardly an expert on this, but...

There are 2 big problems with a 68010 -- move SR,<ea> and the
exception formats. The first you can fix with a trap, the second is
much nastier and lives in the older TOS ROMS. The Germans made a patch
to old TOS that fixes this. TOS 1.6 maybe doesn't have this problem?

However, all the 68010 gets you is faster integer multiply and divide,
plus maybe loop mode now and then. You can get the same speedup using
a 16mhz 68000 with no cache. JRI used to make such a critter and sold
it for a mere $99. Even when it's running at 8mhz, the many-cycle
instructions such as integer multiply and divide go twice as fast.

So, if you can still get the JRI thing, it's a lot better because you
don't have to worry about incompatibilities. Or, you can put up a
larger amount and get a cache, which shows a real speedup.

1057. ICD Booter

Newsgroup: comp.sys.atari.st.tech
Date: 1991-01-15 21:42:35 UTC
From: ekrimen@ecst.csuchico.edu
Message-ID: <1991Jan15.214235.10939@ecst.csuchico.edu>

Graham, we only are compatible with mass storage media that is accessed through ACSI<->SCSI adaptors, like ICD's. The software and logic incompatabilities
made it impossible for us to get the Mac's _SCSIDispatch to work right with ACSI stuff.

So, we stuck the correct SCSI chip at the correct address with the correct wiring-pinouts to match a Mac Plus in the MegaTalk board, and THAT will accept hand-scanners, etc, in Mac mode, plus hooking into Appletalk or LocalTalk networks.

Hope this clears it up. Good question!

But please, a 68010 != a faster 68000!

There is a different expection/trap format for the both chips.
Tos assumes it is a 68000 and thus will fail.

Same problem occurs with a 68020 and a 68030. (probably 68040 as well --
haven't seen any spec's about him).

1064. Re: Setting a 2000 year date *HELP*

Newsgroup: comp.sys.atari.st.tech
Date: 1991-01-16 11:24:38 UTC
From: hvaalde@cs.vu.nl
Message-ID: <8760@star.cs.vu.nl>
Source record: 49451

I checked the problem on my computer 1040STf running TOS 1.0 11/20/1985 and
on a 1040STE running TOS 1.6 (don't know the date)

As Allan Pratt stated the problem lies entirly in reading the year byte
from the keyboard clock what happens is the following

The 'clockvec' vector from the Kbdvbase structure reads the year byte
from the keyboard procsessor
It is converted from BCD format to normal binary form
an offset of 80 is substracted which ofcourse is correct if the year was between
80-99 but is wrong for years from 00-79
in this case one should add an offset of 20
if you don't you have a very wrong year number which according to the GEMDOS
format indicates the year 2028

A simular bug is in the Settime code when writing the year byte to the keyboard

I am trying to write a patch for it and a small test program which shows the
problem, but I don not have much time so it is coming slowly.
One problem I have is the fact that I must use undocumented and ROM depend
addresses

If some one wants to help me, please email me (hvaalde@cs.vu.nl)

1065. Problem with GE_SOFT host adaptor and TEAC SD-340 drive

Newsgroup: comp.sys.atari.st.tech
Date: 1991-01-16 16:01:55 UTC
From: euaanu@eua.ericsson.se
Message-ID: <1991Jan16.160155.2690@eua.ericsson.se>
Source record: 49454

I have a strange problem with my GE_SOFT host adaptor
in combination with a 43Meg TEAC SD-340 hard drive. The
problem is as follows:

First I run the installation program which formats the
disk, creates the partitions and installs the auto booting
driver. It works OK.

Then I turn off and on the machine (a 520 STe with 2Meg) and the
hard drive. The driver is loaded from the hard disk and it shows
the partitions installed. The C: icon is presented on the desktop.
If I double-click on the Harddisk icon I get a alert-box
saying that data on drive C: is corrupted and that it can't
be read.
If I start the installation program (GE-INST.PRG , version 3.2)
and exit it immediately without doing anything then I can access
the C: drive without any problems!!! It seems that GE-INST.PRG
does some accesses to the drive to read the drive type and this
solves the access problem to the drive. I can now copy files
to the hard drive and execute programs from it.
BUT!!! I can't boot from it and I can't boot from the
floppy either if I want to have access to the hard drive.
This means that if I want to use the hard drive I can't have any DA's
or any AUTO folder programs.

Any suggestions on how to solve this problem.

PS. I tried a Quantum 52S drive and it worked without any problems DS

1066. HELP ICD formatter won't format QUANTUM QA250

Newsgroup: comp.sys.atari.st.tech
Date: 1991-01-16 16:07:40 UTC
From: tpj@iti.org
Message-ID: <tpj.664042060@achilles>
Source record: 49455

== Please respond via e-mail to address at end ==

I'm trying to make an ICD hostadapter use a Quantum QA250 ('goldtop', 40 MB). Even if the disk isn't supported by the ICD software (it doesn't appear in the list in ICDFMT.DAT), I should be getting more response.

Symptons

-1 Power up harddisk, wait for usual SCSI bipping signalling drive running.

-2 Power up ST, with floppy A from the ICD distribution in the drive (the disk with an autofolder)

-3 Observe harddisk lamp flicker as part of booting

-4 start ICDFMT.PRG

-5 press key, ICDFMT looks for drive

-6 ICDFMT reports QUANTUM QA250, SCSI ID 0 LUN 0 as only drive found

-7 there are three buttons in that box, [rescan] [continue] [quit]
If I hit [continue] (with mouse or ENTER) nothing happens. !!!!!!!!!!!!!!
If I hit [rescan] or [quit] the program does what it's asked to do.

Setup:

ICDFMT.PRG v 3.10 date 10-10-89.
ICD adapter bought in 1990 (one flying resistor on the print..).
Atari ST with TOS 1.2.
QUANTUM QA250 (ROM r A) with rightmost jumper (end away from address) in, all other out.

The Atari is able to see the ICD clock (using the ICDTIME.PRG), so the adapter is at least connected OK.

I have diagnosed that the QA250 doesn't appear in the ICDFMT.DAT file, i.e. that the drive isn't supported, but I thought that I should at least get a message to that effect (the choice of OTHER in the drive type select menu after the drive scan dialog).

To compound the problem, I have lost my printed ICD manuals (by the simple process of moving from Copenhagen to London).

Please send any hints/advice etc by follow-up or e-mail to the address below, since this is posted by a friend

From: ric@mcrware.UUCP
Message-ID: <4677@mcrware.UUCP>
Source record: 49456

Technically Reclined Netlanders:

I have a 20Meg SH204 Atari Hard disk. I want to upgrade it to a 40Meg SH204.

My understanding so far is:
* there is a host adapter in the shoebox with a SCSI edge connector
* I should be able to hook up "any" SCSI disk to that host adapter

I tried hooking one up last night, but Supra nor Atari's formatting
software wanted anything to do with it.

What I am unsure of is the following:
? What sort of software (whose) will be required to format the thing?
? What SCSI ID should the drive be set to?
? Does anybody have any experience with doing this? What drive did they
use? Software?

Any replies (EMail or otherwise) would be greatly appreciated.

Just a quick note to let folks know about the IC AdSpeed ST 16MHz accelerator.

I bought one from MicrOtyme for $229. Had it installed by ICD for $40. I love it! I have been spending most of my time in PageStream lately. It really speeds it up. Is seems to be compatible with all my software. The only thing it causes trouble with is my QMI Deskcart (maybe it does'nt like to be read so fast?). It speed up Flight Simulator II without any adverse effects.

The general speed up is around 66%, but can be much faster if the code contains loops that stay in the 32K on-chip cache.

If you're considering an an accelerator, go for it!

|> Is there a program that will 'reveal' hidden files on the atari?

Universal Item Selector III (and II) have a switch to control file selector behavior, one of which is "show hidden". Disk editors which look at the directory will show them. Many of the available command shells will show them in a listing.

|> STMirror on my drive and discovered a hidden file (Neodesk.dat) and I think

|> what's in it and why it's there.

Well, your Neo3 manual states that this is where the "volume name" goes, unless the volume has already been named by a formatter using the "directory entry" method in the root volume. It's unclear to me why the characterization that Neo "sucks", except out of surprise at finding something you didn't understand. The fault seems to be more yours, in not reading the docs, than theirs, in creating this behavior. Watch out for the behavior of the recoverable trash can - it is documented to use this technique, as well as "not following expected behavior" to do what it does.

1072. SM124 monitor problem

Newsgroup: comp.sys.atari.st.tech
Date: 1991-01-16 20:12:24 UTC
From: bright@ccu.umanitoba.ca
Message-ID: <1991Jan16.201224.10267@ccu.umanitoba.ca>
Source record: 49462
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

I've got a problem with my SM124 monochrome monitor. A few months ago I started to loose the left-hand edge of the display -- i.e. characters in the first column of the display were squished into about half their normal width. The problem has gotten progressively worse, until the point where I can just barely read characters in the second column (the first column has pretty much disappeared entirely). Fortunately I use mostly GEM applications, so I can move the window to the right in order to keep things readable, but if the problem gets much worse I'm going to find myself back in the days of 40-column displays.

I'm sure the problem resides in the monitor, since connecting it to my wife's 520ST doesn't help. The monitor is about 3 years old, and has seen very heavy use. Does anyone know:
(i) what's causing the problem?
(ii) how to fix it, short of buying a new monitor?

Thanks alot for any advice, BBB

> of keeping time. This is too bad. If you have a clock chip, either

I remember reading something about this awhile ago. But form what I
remember, the way it was supposed to work was that any number less than 85
was supposed to be 20xx (i.e. 2084) and any number between 85 and 99 to be
19xx. (the number being the two digits from the keyboard regarding year.)
But TOS would be able to figure out the correct date, maybe the code has
changed from 1.0 - 1.62 somewhere along the line?

NeoDesk stores the "drive name" in that file. If you click on the
drive icon then select "Show Information" you'll see a place where you
can change (or remove) the name. If a drive has a name, it will
appear in the bottom line of any window open on that drive.

They went this route since GEMDOS (and DOS) only allows 'volume'
labels to be 12 characters, just like a filename. In the older
versions of TOS it was also rather tricky (from a programming point of
view) to change a volume name once you'd set it.

The NEODESK.DAT file just contains the name of the drive that is put
at the bottom of the window. Y' know, when you hit CTRL-LEFTbutton
at the bottom of the window, and type in a name for the drive,
NEODESK.DAT is where the name is saved. I use Universal Item Selector
for seeing hidden files. There are other programs that allow you to
see hidden files, although none come to mind at the moment.

Then again, you could have read the manual to find out about NEODESK.DAT. ;^)

I guess what annoys me is that it's a hidden file. I don't understand why the
file couldn't just reside in the Neodesk directory. Actually I think NeoDesk
is great. What I want to know is how to make it unhidden and/or delete it?
I'll have to reread the docs to see if they mention anything about this. My
feeling is there should be no such thing as a hidden file.

I am currently spending some spare time writing an application for my ST, and I seem to have come across some strangeness.

Does anyone know why the MWC CSD debugger might be having trouble with global variables?

I am running TOS 1.4, 2.5 meg, csd 1.0, MWC 3.09.

Apparently CSD is casting the variables incorrectly (I think). When I view variables they are printed incorrectly, but the code seems to run.

Am I running the most recent versions, or should I try and contact Mark Williams?

BTW, I've compiled and run the same code on Laser C with no problems (under the debugger as well).

Source record: 49468

Atari uses the Write enable line for disk change, Some OEM drives do not toggle this line when the disk is removed, this can be changed by disabling the disk in switch, Note: Gemdos is polling the drive all the time, some drive do not respond to this poll if there is no disk in, so that the write enable line is not toggled, I have a NEC FD1037A and find that they work ok. Note: it is posible to Run a HD drive with some mods, one that is posible is to change the Clock to the WD1702 controler ic. the Germans have done it this way, also change the controler for the 8" type, this is the format used for HD disks, there is a kit for both the other from the USA, but please use some short screen leads...to the drives also the drive case could need a earth...
I do have a Chinon in my ST and it works ok. but did have the Disk change problem, disabled the disk in switch...but that does cause a small problem , the drives will run without a disk in them...

In <2626@krafla.rhi.hi.is> I wrote:

>I've narrowed down the possible causes for the problems I encountered with
>dual Chinon FX357 drives.

Even more so now, but am still puzzled.

>2) it is not caused by heat,
>(only worsened by it, there are only two states: Drive A: functions correctly
>or drive A: consistently reads the same garbage.

It is ?not heat but using the drives which sets it off. Once it is confused
a power-up reboot will not clear it, but switching on after a period of rest
does (still warm but capacitors discharged?). I have found no guaranteed
repeatable way to set it off, other than using the drives and the passage of
time. Once only has the A: drive read a DS disk correctly after continously
failing to read correct. It was pure fluke and I have no explanation for it.
This was during a long test of swapping disks, swapping between drives and
changing write-protect status on the disks. The weirdest behaviour is when both
drives contain writeable disks and both drives have GEM windows open. Removing
a disk gave GEM/TOS conflicting information. The disk eject is not detected
because the disk has its write-tab closed, yet attempts to close the GEM window
cause accesses to the empty drive (which doesn't happen if the disk is in the
drive). The disk has to be reinserted to escape from the retry/cancel dialog
box and subsequent mouse-clicks in the GEM window now cause a directory update
read from the disk, over and over. (???)

More info:
A: drive will always cope with SS formatted disks correctly, at all times and
will robustly format a disk to SS.
TOS reports approx 360 MB format capacity after DS format on drive A:, the disk
is read as empty and cannot be written to (reports "cannot find folder or
application" error).
An empty DS disk formatted on drive B: can be written to and read back correctly
on drive A:, drive B: still sees it as empty even after a directory reload.

>5) I doubt if signal termination is a problem. The dual drive setup works 100%
>if one or both of the drives are standard DD types.

What is actually going on here? Most of the time HD drive A: reads/writes
garbled data and then only under these circumstances:
1) Drive B: is HD, connected with both plugs, *and*
2) Drive A: contains a disk of DS format
also: drive A: can still write/reread preformatted DS disks but pulling the plug
on drive B: will make such a disk unreadable to A: and normal data disks
become readable again. This appears to be more complicated than conditions

1) and 2) above.

>I can probably "fix" this by simply cutting a few wires in the cable,

I have tried disconnecting wires 1,3,5,7,9 between the two drives.
There was no perceptible difference in drive behaviour.
I still have no info on these signals, any takers please?

There is a program called Craft-2 distributed by Hi-Soft. It is a
shell that tries to look like unix, and does a very good job.

To command "ls" will list the directory, and the command "ls -a" will
list the directory with hidden files. The command "chmod" can be used
to change the attribute bits of files (to hide/reveal them,
mark/unmark them as system files, set/reset the archive bit etc.).

Craft is my preferred shell - I like it much better than NeoDesk. It
is particularly well suited to creating an environment that is ideal
for program development due to the sophisticated shell scripts that
can be created.

Hidden files are fact of life, get something (UISII or III, gulam,
etc) to deal with them. They are *usually* not dangerous, as in this
case, where NeoDesk is simply storing your partition name in the
hidden file.

> There is a program called Craft-2 distributed by Hi-Soft. It is a

To each his own, my preference is a combination of graphic and text shells.

> Red/. (speaking via jennie)

Many CLIs will do what is described here. It reminds me though, of Gemini,
any news about when GeminiUK >= 1.2 will show up here?

You might want to check out Gemini (or Mupfel & Venus separately on Tos 1.0).
Mupfel will do this (as will the Neodesk Cli to be fair, but Mupfel is
nicer IMHO 8-). You should know though, this was written by a die hard Neo 3
user 8-).

This is the file that contains the volume name you've given that hard disk
partition. Nothing to be too concerned about...

++ Graham, we only are compatible with mass storage media that is accessed
++ through ACSI<->SCSI adaptors, like ICD's. The software and logic
++ incompatabilities
++ made it impossible for us to get the Mac's _SCSIDispatch to work right
++ with ACSI stuff.

Understood that Mac s/w won't be able to use hardware which is designed to
the ACSI i/f spec, e.g. ACSI HD's.

However, my setup is a couple of ST506 mechs driven by an Omti 3527A RLL SCSI
controller card which is connected to the ST via an ICD ACSI-> SCSI host
adaptor. Which would seem to satisfy your criterion stated above.

As far as I understood, having the ICD SCSI adaptor gave me "true" SCSI. I
wanted to explore the possibility of hooking up either a scanner or a CD-ROM to
the SCSI bus made available by the ICD ACSI->SCSI adaptor.

Your comment above suggests that this *is* possible. However, since posting the
query, I have been told that SCSI devices on the Mac tend to want to talk
directly to the SCSI chip and hence don't work under Spectre. So far no-one has
been able to give me a definitive answer and with CD-ROM down to 280-odd pounds
(from Corporate Computing, advertising in the UK edition of Computer Shopper)
and with Atari being so recalcitrant about re-marketing the CDAR stuff, I
thought it'd be a good route to follow.

++ So, we stuck the correct SCSI chip at the correct address with the
++ correct wiring-pinouts to match a Mac Plus in the MegaTalk board, and THAT
++ will accept hand-scanners, etc, in Mac mode, plus hooking into Appletalk or
++ LocalTalk networks.

This is, of course, the best solution --- for those who have Megas --- guess
which I *don't* have (sigh).

++ Hope this clears it up. Good question!

It's given me renewed hope anyway! In view of the most favourable
interpretation of your answer, I'll see if I can lay my hands on a
SCSI-connectable scanner & s/w and see if it cuts the mustard.

Cheers,

Graham

>What is the "right way" to read the state of the joysticks, and return
>everything to normal after I've finished ?

I've done it, but the method has been tucked away in a code module
for quite a while now... Basically,

1. Adjust the joyvec to point to your routine
(I think you use an XBIOS call to do this)
2. Tell the IKBD to send joystick packets for each joystick
position change. (an XBIOS call again)

3. Before you quit, re-enable the mouse.

Your routine is a parameterless procedure, and the joystick
values are contained in some registers. I'm a bit vague on this part,
so if nobody has any accurate data, I'll post my code.

I'd say it is right, I works on a 520 and a Mega 4, so that's enough
for me.

1087. MAC 128K ROMs to barter (or sell as a last resort)

Newsgroup: comp.sys.atari.st.tech
Date: 1991-01-17 23:36:03 UTC
From: kron@aiki.Central.Sun.COM

Cross-posted to: comp.sys.atari.st.tech,comp.sys.mac.wanted,comp.sys.mac.hardware,comp.sys.atari.st

I think I've managed to barter a few sets of 128K ROMS (haven't closed
the deal yet) so if anyone is interested I would be willing to
sell/trade. I'm looking for a color monitor (used is fine) for
the ST. As well as software development stuff for the MAC.

>Hello,

yo...

> I am trying to write a shell program (due to the idiosyncracies of gulam),

join the club...i, too am doing this, which makes me wonder why we can't just start with gulam source (unless, of course, the author used ATT/BSD code :-).

>I have made several attempts to do input/output redirection with varying degrees
>of success. Please could someone out there tell me the 'proper' way to redirect
>IO before a pexec call (thinking in terms of a shell program). Do you have to
>preload the program, do the redirection, and then re-pexec, etc.

normally, u use Fdup/Fforce to force stdin/stdout/stderr handles to open file handles. the shell opens the files before the Pexec and closes them after. i don't have code handy, or even a man page, so in general, do:

1) parse cmdline, looking for redirection

2) if so, open the file names (or pipes)

3) Fforce std device handles (stdin, etc) to the open file handles (i would think about opening the files binary, rather than text, as well)

4) set up the command and do the Pexec

5) on return, close the files.

note that i recently posted a reasonable popen/pclose, though the MiNT versions would be better.

you can also do something like this:

```
sprintf (pcmd, "%c%s %s >file", (char) strlen (cmd), cmd, args);
Pexec (..., cmd, ...);
```

tho i have only been able to redir stdout this way (not stdin). this is probably not recommended, at least by me (and doubtless those code police out there who will no doubt jump on me), but it is quick (and dirty). this does not work for all programs. the Fforce should, however.

i have written a tiny shell, invoked by my cc(1) to start the various passes of alcyon, which normally cannot be redirected by gulam. i can mail it to u if u want.

along these lines, for those of u that are writing a shell, i would offer these suggestions, based on lack of features in gulam:

1) pipes are a must, i.e. "ls -l | grep xxx | wc -l"

2) args in quoted strings include spaces, i.e. grep "a string" file passes "a string" as a single arg to grep, with an imbedded space

3) make it portable

4) support MiNT (and add job control, if possible)

5) RELEASE SOUCE CODE!!!! then the rest of us can improve your work (and be more productive, since YOU also benefit from these improvements)

6) personally, i like history accessible via emacs/vi/cursor keys a l tcsh/ksh.

7) command prompt should be able to deal with imbedded escapes (i.e. ESC p/ESC q for reverse video). gulam gets confused

8) make it possible to redirect inside scripts

9) make it possible to do things like "sh file" (or, if memory serves, "echo 'command' | csh -s")

10) loadable common programs (cat, ls, grep, etc) which stay in memory (i'd rather have them in /bin, too)

11) support something like SLASHCHAR env variable, so cmd lines can use either "cmd /path/file" or "cmd \path\file". shell translates according to SLASHCHAR before exec'ing cmd. it would be nice to support alternate device names, e.g. "/dev/c" for "c:" in cmd lines and scripts.

12) soft links would be a definite plus, if u feel ambitious...

these are some of the things i would do to, if/when i write my shell. i would also do away with builtin emacs/file xfer, etc. there are plenty of good standalone codes for this. still, gulam has served us well for all these years. and it is very solid, at least in my experience...

pleasant programming....

Note: The drive select lines and the side select are not buffered, they
are just LPTTL, this is easly overloaded with the pull up resistors that
are fitted to OEM drives, use a LPTTL IC O/C that can drive into
500 ohms, the normal pull up resistor for OEM drive are 1 K ohms, so
with 2 drives that will be 500 ohms, If I remember the IC is 74LS05, but
correct me if I am wrong, Atari use about 2.7 k resistors in there
drives...

A friend of mine runs a ///Turbo Board ST system. He has two computers set up, each running a copy of Turbo Board. However, he has no way of communicating (i.e. teleconference) between the two computers.

We originally had a door that let two users chat over the midi cables. However, you can't page other users, or know when they are on.

We tried SGS-Net and MidiNet (from MX2). However, Turbo/FoReM are extremely stubborn in that respect, and bug up when you try and use them.

What we would like to know, is is there an efficient method of networking the hard drives on bother computers together, as well as maybe a ramdisk? This would simplify it greatly.

I hope you can help,

From: neil@cs.hw.ac.uk
Message-ID: <5259@brahma.cs.hw.ac.uk>
Source record: 49483

This has probably been mentioned before but ...

Wouldn't it be a nice idea if Atari were to assign a desktop info file
entry to application use.

eg. #+ APID PR#1 PR#2 ...

Where #+ would be the unique (and as yet unused) identifier for an application
line, APID would be for the application to identify lines that were for it,
and PR#1 etc would be the parameters for the application.
APID's would work in a similar way to Cookies and XBRA id's in that ones that
begin with an '_' would be reserved for Atari applications (Maccel etc).

This would mean that application and accessory configurations could be saved
in DESKTOP.INF and reconfiguration take place with shel_get/put. (I know the
buffer has a maximum size TOS 1.0-1.2 1024, TOS 1.4 4096)

If Atari have not got this in mind already perhaps they would like to give it
some serious consideration. Anyone else like to comment?

The joystick routine called by the XBIOS gets a pointer to a status block (in A0, I think). The first byte identifies the joystick that caused the event, the second and third byte contain the current values of joysticks 0 and 1.
You should be somewhat careful about saving registers in your joystick routine, and make it short. I usually copy the joystick values to some global variables which are polled by the program.

Hope this helps.

1096. PC Serial Mouse to ST

Newsgroup: comp.sys.atari.st.tech
Date: 1991-01-18 16:52:24 UTC
From: dalessio@motcid.UUCP
Message-ID: <5618@feldspar23.UUCP>
Source record: 49486

I have asked this question a couple of times and received
a few responses, but none to actually answer my question.
I hope someone can help.

How can I connect a Microsoft compatible SERIAL mouse to
my ST?

I have seen messages telling how to connect a bus mouse to
the ST, but not a serial mouse. Some people from comp.sys.ibm
have told me that a serial mouse and a bus mouse are the same.
So I believe there should be a way to connect a serial mouse
to the ST. I cannot find bus mice sold separately from the
cards (anyone know of a place?).

Thanks to everyone who responded to me, and thanks for any
new help!

1097. NEC 3D and IB Multisync switchbox

Newsgroup: comp.sys.atari.st.tech
Date: 1991-01-18 22:08:27 UTC
From: ekrimen@ecst.csuchico.edu
Message-ID: <1991Jan18.220827.4568@ecst.csuchico.edu>
Source record: 49487

After having my NEC 3D for almost two months, I have <<<*FINALLY*>>> gotten a switcher that works and works WELL.

I'm not going to go into detail about how I ended up with what I ended up with, but I spent *A LOT* of time waiting for things to arrive via UPS and I made A LOT of phone calls trying to iron things out.

Before I tell you what I have, lemme say that you should avoid the Omniswitch like the plague! I went through three of them and they were all bad. None of them worked with my NEC 3D. One of the places I called about the switchbox I have now won't even carry the Omniswitch because he knows they are sh*tty.

I am now using an IB Multisync switchbox. IB Computers of Beaverton, Oregon distributes them; they are made somewhere in Europe. It's a very sturdy, well-designed, and well-built box. It's made of metal and measures about 2"x3". It has audio out and audio in ports. It has about an 18" cable going to the ST and a very, very long cable for the multisync. At the end of the multisync cable is a *male* 9-pin plug, which I thought was kinda strange, but IB says that only within the last few months have multisync monitors become rather standardized. Therefore, I needed a female 9-pin to female 15-pin converter since my 3D has a male 15-pin plug; I got that from a place in Computer Shopper called DALCO, since I got my NEC 3D used and it didn't come with one. The switchbox retails for $70, but can be found for less than $55. It uses a 9V, 500milliamp power adaptor that I needed to sync in monochrome so I used the one from my Atari 2600 in the closet.

So what's the verdict? Do I like it? Yes, I like it very much. Was it worth the effort? Yes, I think so. The NEC 3D is a VERY nice monitor. I saw the Acer/Omniswitch combo at my dealer; to test it, I typed in a small note using NeoDesk 3.0's desktop notepad feature and I couldn't even read what I wrote. NeoDesk uses a 6x6, the smallest font, and it was very difficult to read. I did the same on the 3D and it was crisp. I won't vouch that the 3D is as clear as an SM124, but I don't need a magnifying glass on the 3D's 14" screen to see the 8x8 or 6x6 fonts. I'm not as picky as others about the sharpness of the monochrome monitors, but the 3D comes quite close. The color on the 3D is also extraordinary. With the Omniswitch, the reds were pastel and the screen was very large, even though it was shrunk down to its smallest size. Whatever the IB switchbox has done differently, it does it well.

I saw the Sony CPD1302A at a friend's house. I've heard from several people that it's better than the 3D for connecting to the ST. I regrettably didn't examine upclose the clarity of the monochrome, but it and the color both looked great. The screen adjustment controls are at the back of the 1302 which is a disadvantage; they're on the front of the 3D. The mechanical click of the 1302 syncing could also be heard when switching between color and mono.

So there ya' go. As always, if you have any questions, you know where to reach me.

MWC's CSD is flaky as all hell. I am surprised your actually trying to use that thing. If your doing something that complex, that you need a source debugger, I would trash MWC and get Borlands package.

THERE are a LOT of strange things that compiler system does for the ST, if you don't at least have version 3.0.6 I really question whether its useful for anything but light and medium-light jobs.

There has been quite a bit of discussion about whether SCSI devices will work with the Spectre and ST world. I don't have a Spectre, so I can't specify for that machine, BUT the components DO work!
I bought an ICD host adapter, and an ST296N mechanism, (with power supply), and had that running just fine on the ST...after a while, I decided I needed more storage on my Mac plus. I had two 20MB Mac harddrives.
All I did was switch the SCSI mechanisms. I took the two 20MB mechnisms, and hooked them into the cable coming off the back of the ICD, and put the 296N on the cable on the inside of one of the 20MB cases. Boom! 40MB on the ST, and 85MB on the Mac. It worked.
What I'm getting at is that the mechanisms SHOULD work interchangably, right? If the ST can 'see' the SCSI device, then is there any reason the Spectre won't? Seems like you'd just have to format a spectre-specific partition, and you're off and running...

The SCSI-Spectre incompatibility problem probably has more to do with the
way the Mac software deals with SCSI.

Dave Small seems to have written software to convert the Mac disk file I/O
into something that the Atari/GCR can do. Mac SCSI devices probably demand
more specificity and might even bypass the OS software if it is inadequate.
If the last thing is not the case, then there might be a software (non
megatalk) method of using Mac SCSI devices on the ST. Of course, since
Small was revving up with appletalk compatibility anyway, it probably made
more sense to do SCSI in hardware anyway.

> Is there a commercial pakage to perform this?
> ANY help/info would be VERY appreciated!

Well, there was a guy who lives here in Austin, Texas who did something kinda interesting along the lines you descibe, although I'm not sure its exactly what you want. He ran a Fido board on his ST called the Database for a while. It was a most unusual setup. He had an ST with a plug-in cartridge that gave him a second RS-232 port that he had bought in Germany when he was stationed there. He also had a PC with several hard drives and a tape backup unit. He ran PC-Ditto (software version) on the ST. He ran a TSR on the PC and the ST (running under PC-Ditto) that made the PC act as a file server to the ST (or visa-versa if he had wanted I suppose, but he didn't have all those hard drives for the ST). I don't remember the name of the TSR, but apparently it allowed one PC (or an ST that thinks its a PC) to get files from the other PC over a serial null-modem connection transparently to the software. The software thinks its accessing a disk drive (it is, but its on the other PC).. Anyway, he ran Quick BBS on the ST under PC-Ditto and kept all the big files on the PC, accessing them as if it were a big disk drive.
I realize its kinda complicated and not exactly what you asked for. But I thought it was an interesting tidbit and couldn't resist it.

The following opinions are my own and not those of anyone else who might be registered on fquest.fidonet.org. All flames can be sent to alt.flames since we don't read that here.

Yep, it'll work just fine. A friend who owns a PC compatible and I used
KA9Q to connect our machines together over the phone lines at 2400 baud and it
worked without a hitch. We tested FTP and TELNET with no problems. If you
want, and can throw together the necessary hardware, you can get even higher
speeds using the MIDI port. If I ever get a TT, I'm going to use KA9Q to
network the two machines together.

I've forgotten which FTP site has the most recent version. Anybody else
know?

In the Docs for KA9Q I remember reading about a simple modification for the MIDI ports that would allow them to do the standard 38.4K of serial ports, which would help the speed problem. Does anyone have anymore information about this mod?

On another related note, there was a set of prgs that allowed to ST's to be netowrked of the serial ports. I had this working between a friend of mine ST and mine. His had the hard drive, and they showed up on my desktop as regular drive icons. Programs could be copied just like if the drives were really there. Also, the the server computer (his) could operate normally, with only a little bit of slowdown. But I can't remember the name of the prg though, but I think it is on Atar.Archive.

But if the Midi ports were modified to 38.4K, and the server software modified to run as a TSR on an IBM, then this would be the ideal set-up. It would allow both computers to run uninterupted, and the ST would see the IBM's hard drive as regular drives.

1108. Old Missile Command Game (Arcade Upright Style)

Newsgroup: comp.sys.atari.st.tech
Date: 1991-01-21 03:42:19 UTC
From: aa377@cleveland.Freenet.Edu
Message-ID: <9101210342.AA06030@cwns12.INS.CWRU.Edu>
Source record: 49298

I post this here in hopes that some tech-type from Atari will see it and be able to help me. I have an Old Arcade Missile Command game (Upright version, not cocktail) and I was wondering a few things about it...

#1. Can the monitor inside be adapted to recieve normal NTSC signals (IE. Can I plug my VCR into it without SERIOUS hacking)

#2. Can the Video Signal be easily moved out onto a Composite type monitor?

#3. Is the Trak Ball inside the machine anything like the "Trak-Ball" (Black rectangular looking thing, with triangular buttons on either side) and can I use/convert it to a mouse.

The ultimate goal of all of this is I would like to use the housing for my Amiga1000 (I know, boo hiss ;)

Could any replys be sent to my E-Mail address as well as being posted. Our site gets Atari.st.tech on a "sometimes maybe" basis and I might miss the reply.

Thanks in advance!

Oh! I forgot. Any clues on if it's possible to get an "Operation, maintenance and service" manual for this beast?

Ken Kopin
--
I just typed this in.
No, really; I did.

This file contains the extended volume name for that partition. This is nice,
because you can change it whenever you want, and can use more characters
and spaces. Thus, the bottom of your windows will say "programming" or
"utilities" so you know where you are. I personally think it was a good
idea to make this file hidden, but if you really need to see it the Universal
Item Selector will show it (in light print).

>a MS compatible serial mouse will not work cause they have their data
>already encoded in serial format (at leats not w/ a simple cable.

Forgive me for being thick, but let me as some questions.

1. Is the MS mouse unit (that which has the buttons) the same for
bus/serial versions? That is, where exactly does the serial
electronics reside?

2. If not, then buy cutting the end plug from the serial version
will I have the equivalent of a circumcised bus version?

3. If #2 is true, is there any standard color assignment for the wires
so I can make the famous ST<->MS mouse adaptor?

The basic premise is this: I have an MS mouse SERIAL version, and would
like to hook it to my ST, and would be willing to cut off the end plug.

1111. hooking up vga cards to ST's

Newsgroup: comp.sys.atari.st.tech
Date: 1991-01-21 05:50:14 UTC
From: cstein@jarthur.claremont.edu
Message-ID: <10377@jarthur.Claremont.EDU>
Source record: 49301

Does anyone know how to hook up a VGA card (or super VGA card) to a Mega ST.

I've been thinking about it and it would be pretty neat to do. I wouldn't expect TOS to use it; I was thinking it would be an extra monitor so one could be using the standard Atari monitor while looking at a picture displayed on the other monitor with the VGA card. It would be for display purposes only, not for general use (which would probably involve some major hacking of TOS).

Can anyone help? Has anyone done it?

--Cliff

1112. SIMM / MULTISYNCH

Newsgroup: comp.sys.atari.st.tech
Date: 1991-01-21 07:19:00 UTC
From: jennie@ius2.cs.cmu.edu
Message-ID: <11626@pt.cs.cmu.edu>
Source record: 49302

Two quick questions:

1) Are the ST SIMMS "standard" ie. will 8 bit SIMMS from IBM dealers
work in the ST, and what speed should they be (80ns, 70ns, ...) ?

2) Can a MultiSynch monitor (eg. NEC 2A) be hooked to an ST.
How (I don't have a multisynch yet so don't get too technical -
just an outline will be fine) ?
Will it display all three resolutions ?

OK, so it's really six questions. Can anyone out there in netland help ?
Thanks.

1113. Hidden folders (was Hidden Files)

Newsgroup: comp.sys.atari.st.tech
Date: 1991-01-21 10:48:31 UTC
From: hvaalde@cs.vu.nl
Message-ID: <8800@star.cs.vu.nl>
Source record: 49303

reading about hidden files, I remembered the following:

When I transfer files from a Macintosh to my atari disk (MSDOS format)
the mac always create a HIDDEN FOLDER named resource.rfk (or something like that
Now the problem:

The desktop discard the hidden bit for folders or show them as files (I think)
Neodesk does it correct and doesnot show it ever (version 3.x, 2.x shows it
as a file)
LGSELECT show the hidden folder as a hidden file

How should I delete the file in the folder and the folder itself?
(I found a rather complex way but it shows that several people never realise
that folders too can be hidden)

Just a brainwave form Harold van Aalderen (hvaalde@cs.vu.nl)

Source record: 49305

warwick@batserver.cs.uq.oz.au (Warwick Allison) writes:

> 1. Adjust the joyvec to point to your routine
> (I think you use an XBIOS call to do this)
The vector to be changed is found using the Kbdvbase() function which returns
a pointer to a structure which contains the joystick vector at an offset of
0x10 I think
Changing this vector should be done before telling the Keyboard processor to
send joystick information to avoid changing the vector during an interrupt.
Changing the vector cannot be done by any Xbios call or any other system call
for that matter.
Since the routine is executed during an interrupt it should be sort and fast
(maximum 1ms = about 1000 instructions) you cannot use any BIOS XBIOS GEMDOS
calls or any routines form VDI or AES during the interrupt.
A pointer to a packet containing the joystick information is found in A0
you are free to change the registers A0,A1 D0,D1,D2 without saving them (I think
end the routine with an 'rts' instruction

> 2. Tell the IKBD to send joystick packets for each joystick
> position change. (an XBIOS call again)

You can tell the keyboardprocessor to send joystick information using the xbios
function Ikbdws().
It is a could idea to have your interrupt routine just copy the information
of the status packet to some global variables. any setting another global
variable (say JOY_VALID) to tell your program that the information is valid
Your main loop can than read its own global variables when the JOY_VALID is
true and set it to false when it did so. this loop can offcourse call any part
of the system whenever it wants to.

> 3. Before you quit, re-enable the mouse.

This can be done easily with Ikdbws() using the keyboard commands for
'report relative mouse positions'

The proper keyboard commands and the format of the status packets can be found
in several books about the Atari
for instance: 'Atari ST intern' or 'Ataris ST Profibuch' (do not know authors)

DISCLAIMER: Information given is based on information read in books mentioned
and some own experience from reading mouse information this way it is never
tried by me in practice. Therefore I cannot be hold responsibly for any kind
of problems or damage resulting from using the information given by me.

(short I don not know if it is correct)

From: jkr@ifi.uio.no
Message-ID: <1991Jan21.115306.17458@ifi.uio.no>
Source record: 49306

I just thought about this the other day, it might have been discussed before:

With a 32bit address bus (such as the 020) you'd have a compatibility problem
with negative short word address mode sometimes used for chip-access
in whiz-bang programs. I am quite sure I've seen assemblers that store
$fffa01 as 00 FF FA 01. On the other hand some assemblers allow you to write
this address as $FA01.W for faster access (some assemblers even optimize with it).

My revision of the developer system doesn't say anything about this. Are the
chip register adresses defined as a negative offset from the top of the addressable
range or as the absolute address 00 FF FA 01 ?

>How much shall I be prepared to spend? Finally, will Atari HDX deal with it?

Remember you have to use drives with an ST506 interface in a Megafile 20.
By the way, in Germany, there has never been something like a Megafile 20.
Is this the same as the old SH205?

Back to the original question: Any ST506 MFM drive should work. HDX can
be customized to handle the new drive by inserting a drive description#
into the WINCAP file.

From: bointon@kcl-cs.UUCP
Message-ID: <1935@xenon.kcl-cs.UUCP>
Source record: 49309

Does anyone out there use more than one drive at once on a GE-Soft interface?
I have a couple of drives that refuse to work together for very long. I have
checked out the usual things- different SCSI addresses, termination resistors,
power supplies etc. Many of these have been eliminated by the use of separate
power supplies and 2 interface boards (The problem persists on both the SCSI
and DMA chains). What seems very odd is that everything works perfectly to
start with, but after about 15 mins, things start to fall apart one partition
at a time (general corruption all over the place).
This sounds like a software problem to me- can anyone shed any light on this?

BTW the disks are a 48M 30ms Seagate ST157N-1 and a 40M 11ms Quantum P40S
(nice drive!). I also tried all possible combinations with a Syquest SQ555.

Thanks,
Marcus Bointon.

1120. Static RAMs please!

In talking to someone about the MS serial and bus mice, I found out
that within the serial mice there is some electronics to convert the
output of the "rolling sensors" (don't know the official name) to
the serial data a serial port requires. He said that in order to
use a serial mouse with the ST, you have to open the mouse and
reroute the "rolling sensors" output directly out the mouse plug,
bypassing the electronics.

He is going to help me do the conversion. If I can explain it
(I am not electronically inclined), I will post instructions
on the net.

On the TT they solved this by mapping $FFxxxxxx and $00xxxxxx to the
same physical address, so $FFFA01 == $FFFFFA01.

I'm not certain (I don't have the TT developer docs), but I believe
the recommended method is to use $FFFFFA01. What to do for the
cartridge port is the problem, since it's not in the $FFxxxx range.

>in the closet.

I'm surprised a power supply is needed. I've built a cable (RF nightmare, I'm sure, but the picture quality is perfect with the Sony 1302) which has a headphone jack for audio and a switch for mono/color switching. No need for a power supply, the switch grounds the mono detect line when in mono mode from the ground connection of the monitor port. It's ugly, but works perfectly, and the headphone connection allows me to use my powered speakers for awesome sound, or a small amplifier I built around Radio Shack's amplifier chip for ~$10 with headphones for non-powered speakers. Perhaps the IB switchbox has an amplifier in it for which power is needed? Anyway, my setup just looks like a serial cable with a headphone socket and an ugly pink toggle switch a few inches from the ST end. I've hardwired the nine-pin female connection for the Sony, but would be easy enough to rework for other connections.

You can make ANY file think it's a folder by fiddling with GEMDOS(67). This call will let you read or write all the file attributes for anything on the disk, HIDDEN, SYSTEM, PROTECTED, all that. I shudder to think of what's going to happen to the disk structure if the file isn't actually a folder, though. A friend of mind was goofing around with folder structures and managed to put a folder inside itself, transforming it into Rusty the Undeletable Folder..
And to whoever was trying to find out what hidden files are on his harddrive, START just published my "Hide-O-Rama." It lets you view and change the attributes for HIDDEN and SYSTEM files. Little Green File Selector also displays HIDDEN files, and I think UIS does as well.
That way to a man's heart is through
his ribcage,
Greg "Maddog" Knauss

Yes, the Atari part number for the Megafile 20 was SH205. Thanks for the
information. I would have maile dthis but I figured some might want to
know what a Megafile 20 was.

From: slh85@cc.usu.edu
Message-ID: <1991Jan21.175157.46716@cc.usu.edu>
Source record: 49316

I was wondering how to program the mouse from C (preferably Sozobon). I've looked at the sources for MiNT and it has something of a sample (in BIOSFS.C) but I couldn't make much sense. I have also tried opening the MOUSE device from within MiNT and I didn't get anything that made any sense. If anyone can help and preferably send example source I would really appreciate it.

I will summarize and post if there is sufficient interest. Otherwise I will just reply to anyone who sends me mail requesting forwarding.

Thanks,

Kurt Olsen

I once called Mark Williams Co with the question "Where is the break key?"
They said, "What do you mean? Pressing F1 will stop a program...."

"But not a run-away program!"

I once worked on a 386 cross-assembler: it was going to run under MINIX,
but MINIX was so unstable then (summer 88) and had the same (flaky)trouble.
Program runs fine under TOS, but the debugger causes mistakes, or even
better, crashes under TOS but runs fine under CSD....

!!
Please note! All mail directed to me should be sent to my new address:

>useful for anything but light and medium-light jobs.

These are fairly strong statements. It would be great if you could
provide a few concrete examples of problems.

There are several problems with switching compilers. The main one is
that my program is uses a lot of the MWC specific features in the
library. These would all have to be converted to a new compiler.
Second, it costs to buy a new compiler. I already have one and I'm
very satisfied with it, except for the debugging strangeness.

But I'm curious. Where can one get the Borland C package in Canada?

Is anyone aware of a profiler that is compatible with MWC version 3
binaries? Some time ago (1987) David Rowley released a profiler for
MWC v2 and alcyon/dri format executables. Has this ever been updated
for v3 executables?

I think this is not possible unless you heavily modificate the motherboard.
I know one guy who has expanded his 1040 to 2 Meg by soldering new chips
on top of the old ones. Dunno if this works up to 4 meg. (4 chips piled, no
room...)
Always use sockets with chips. Otherwise you loose your mind when chips need
to be replaced...
By the way, did you ment to replace 4x256kb chips with 1Mx1 chips? 1Mx1 has
more pins than 4x256kb... Different pin assignments...
Buy a ready-made expansion! Lot easier, and works surely!

The reason for the power supply is that "some" multi-sync monitors need
more current to operate than the ST supplies; thus they contain a video
signal amplifier(s). Many (most?) monitors operate fine at the ST current
levels, thus you normally don't need add-on power.

- Does anyone know how to hook up a VGA card (or super VGA card) to a
- Mega ST.
-
- I've been thinking about it and it would be pretty neat to do. I
- wouldn't expect TOS to use it; I was thinking it would be an extra
- monitor so one could be using the standard Atari monitor while looking
- at a picture displayed on the other monitor with the VGA card. It
- would be for display purposes only, not for general use (which would
- probably involve some major hacking of TOS).
-
- Can anyone help? Has anyone done it?

Don't know if this will help you or not, but I'll mention it anyway.
There's a board called an ISAC board which gives 1024x768x16colors
out of 4096. It costs around $1000 and requires a multisync monitor.
I've never seen one. Then, there's also the Parsec board which does
roughly the same. I think both are GEM- and TOS-compatible with some
patches. I think Lexicor is handling the Parsec board now and a new
place called Dover Research is handling the ISAC. Unfortunately, I
don't have numbers for either. If you want, leave me mail and I'll
look around for some addresses.

- 1) Are the ST SIMMS "standard" ie. will 8 bit SIMMS from IBM dealers
- work in the ST, and what speed should they be (80ns, 70ns, ...) ?

Yes, the ST SIMMs are standard. You can use either 1megx8 (Mac SIMMs)
or 1megx9 (IBM SIMMs) at 120ns or faster.

- 2) Can a MultiSynch monitor (eg. NEC 2A) be hooked to an ST.
- How (I don't have a multisynch yet so don't get too technical -
- just an outline will be fine) ?
- Will it display all three resolutions ?

The NEC 2A won't work 'cause it's not a 'true' multisync. I'm using
an NEC 3D right now. I know others who have used NEC II, Sony 1302,
and many other models. There are some basic guidelines to the type
of monitor you can use.

A pity that Atari didn't document this. This is exactly the same kind of brain-damage that causes the 640 K memory limit on you-know-who PCs.
The whole confusion probably stems from Atari's use of 24-bit addresses in their meager documentation. Did they never expect to use a 68020 in future models ?

My advice is to use 16-bit addresses for hardware registers (if you REALLY must use the registers, that is ...), and cursed be those who don't !

1137. Mouse pointer clipping help please

Newsgroup: comp.sys.atari.st.tech
Date: 1991-01-22 21:39:41 UTC
From: erik@mcrware.UUCP
Message-ID: <4716@mcrware.UUCP>
Source record: 49327

I have a program that runs in low resolution (even though you might load it from medium res), but I am having problems with the cursor.

Right now, to keep the mouse pointer from wrapping around twice when you move all the way to the right side, I intercept the cursor movement vector so that the cursor can not move beyond 319 in the x direction. This works fine, except that when the cursor is near the right edge of the screen, the image wraps to the left side of the screen slightly. This does not affect the function of the mouse but it is slightly annoying.

What I need is a way to tell the machine that the screen is 320 pixels wide, not 640, so treat the mouse accordingly. By a little investigation, I have found a memory location to do just this, but no doubt use of it directly would be "illeal" and may not work on other machines.

Any help would be much appreciated.

Thank you,

Erik R Johnson erik@mcrware.com

If think that the addresses is defined to be in the top of the memorymap eg.
0xFFFF_FA01, and that just happens to be in the reach for a negative short
absolute addressing.

But it should be a simple problem for the onchip MMU, to map the 24 bit
addressing used by some programmers/compilers/assemblers to the full 32 bit
on the TT.

Hello everyone in Net-Land!!!

I was wondering if anyone has or knows of a place where I could find a fast raster drawing routine? I am espescially interested in Low resolution color and monochrome.

Also, does anyone know how the bit planes are set up in the new TT specific graphics modes? In the 320x480x8 mode, does one byte equal one pixel? Life would be so much easier if Atari had set up the screen memory this way, so that raster operations could be performed extremely easily and quickly. Thanks!

Take care!

I am using a 3D with my ST, and there is a simple switchbox with no extra power-supply. This is commercial product. But I also made a interface for it for monochrome mode only, with simply soldering the wires to right pins. I wonder why your switchbox needs extra power? Do you have any clues about the voltage it needs? (Maybe a TTL-level?) What happens, if you unplug this power supply during operation? Are there many components besides the switch and audio connector in that box of yours?

I have read somewhere that the ST puts out a short Frame sync pulse
that does not lock some monitors in the Mono Mode, so they put in a 555
timer IC, this could be what the P.S.U. is for, also I have read that
the later versions of the NEC 2A do work on a Atari, Note the Atari only
has 2 scan modes, similar to CGA/VGA but with Analog inputs, anothere
thing that is often forgoten is that the RGB voltages are 1 volt pk-pk
and some monitors can only take 0.75 volts pk-pk, so to get this voltage
down, just fit 22 ohm resitors in the RGB lines at the monitor end of
the cable...

1145. NEC CD-ROM to ST

Newsgroup: comp.sys.atari.st.tech
Date: 1991-01-23 16:20:14 UTC
From: dalessio@motcid.UUCP
Message-ID: <5651@feldspar23.UUCP>
Source record: 49332

A friend of mine has an NEC CD-ROM drive he is selling.
I am wondering if I can use it with my ST. I have an
ICD host adapter with an OMTI controller running a
Syquest removable. Can the CD-ROM drive connect to this?

If I can connect them, will CDs for the ST work in this
drive?

Sorry, I have no specs on the CD-ROM drive to help. If
they are needed, I will get them later.

Thanks for any and all help!

1146. DESKTOP.INF question

Newsgroup: comp.sys.atari.st.tech
Date: 1991-01-23 18:09:08 UTC
From: bobw@hpsad.HP.COM
Message-ID: <18420005@hpsad.HP.COM>
Source record: 49333

Where can I get some documentation on all the stuff defined in
DESKTOP.INF file?

Maybe somebody can help me with what I want do do:

I want to replace the [show] selection, but not the [print], when
double-clicking a non-executable file with QVIEW.PRG that came with
QUICKST package. Can this be done with DESKTOP.INF file?

Thanks,

Bob

- >
-
- Jennie, don't believe him! I have used Nec 2A with ST, and I still
- have that cable to do so available. The cable is made by Lindy and is
- available at least in Germany. But it is a quite easy one to make
- yourself too.

The reason I said it won't work with the ST is that a couple of people
told me that it won't sync when connected to the ST; therefore, I
didn't risk trying it out, since they know more about it than I. I
don't go around making these things up. :^) Do you get all three
resolutions with the 2a or just color or mono?

1148. Re: Hidden folders (was Hidden Files)

Newsgroup: comp.sys.atari.st.tech
Date: 1991-01-23 18:58:39 UTC
From: apratt@atari.UUCP
Message-ID: <2814@atari.UUCP>
Source record: 49334

Somebody says "MAC copies to MSDOS (Atari) disks create a hidden folder."

Then ss60wbi@sdcc4.ucsd.edu (G. "Maddog" Knauss) writes:
>You can make ANY file think it's a folder by fiddling with
>GEMDOS(67). [...] I shudder to think of what's going to happen to the disk
>structure if the file isn't actually a folder, though.

TOS versions 1.4 and greater do not allow this. They return "access
denied" if you try to change the folder bit to make a file into a folder.
You also can't set the volume-label bit or any of the undefined bits.

You can't change ANY of the attribute bits of a folder. If the folder
bit is set, it has to be the ONLY bit set. "Hidden folder" is an invalid
combination under GEMDOS.

Obviously, it's possible for something illegal to come in from outside. I
really didn't think about this when I put those restrictions on Fattrib.
I'll have to think about that one.

>

I am using 2 SH204 connected to my ST, one addressed at 0 for the disc,
and the other addressed at 2 for my SCSI cartridge tape drive. The
SH204 host adapter boards will only access SCSI device 0 (it's in the
hardware) but with little work, the ACSI (DMA port address) can be changed
anywhere from 0 to 7. The disc interface board is talking to a Maxtor
380 meg XT-4380-S SCSI drive, and the tape is a CYPHER CT-540 SCSI 5.25
inch cartridge tape drive. I use the Supra v 2.06 (I think?) driver
with the controller and drive defined as 'other'. The tape driver is
code that I wrote that installs itself as a TSR attatched to BIOS trap
13 RWABS calls. I wrote a unix like TAR program that I use to perform
backup , restores as well as file transfers from my ST to UNIX system
and vise-versa. I believe you need the 'new' SH204 adapter PAL's tho.

>AAron@sun.soe.clarkson.edu writes:

>>>>and should run about 10% faster.

No, that's not realistic. The most you can get is about 3% to 5%. 5% with programs, wich do *much* arithmetic!

>There is a different expection/trap format for the both chips.
>Tos assumes it is a 68000 and thus will fail.

Yes, that's the problem. But one can get here in Germany a patch-program for some money from a magazine called "c't", which reads the built-in TOS and produces a new TOS (one has to burn it into EPROMS of course) working with 68010/20. I did this work with the TOS-1.2.

But some people are waiting for the release of a (not official) TOS-version called KAOS-TOS, which is said to work with the 010/020/030 and bases on TOS 1.4.

It's said, that it's compatible with ABC GEM 2.2, has no Line-F Code and improvements an the AES and GEMDOS.

One can even improve this program by using the KAOS-TOS together with a new programm call NVDI (= new vdi).

Results from Quick Index for KAOS and NVDI:

TOS text: 286%
TOS string 1075%
TOS scroll 132%
GEM dialog 367%

(numbers from 'ST-Computer, 1/91, page 21)

NVDI is a commercial program.

KAOS was offered to Atari, but Atari-US rejected it. (One can read in our magazines, that Atari-Germany is very interested in this new TOS-version.....)

So the developers are still looking for another way to publish it. Some thought of the release via book, with a disk with a patch-program on it........

>Same problem occurs with a 68020 and a 68030. (probably 68040 as well --
>haven't seen any spec's about him).

I thought, that the 040 is the first processor, which doesn't support
the variable bus-range (8-, 16- or 32-bit), which allows the 020 or 030
to work with a 16-bit architecture like the ST oder Amiga(500/2000).

HELP!

My beautiful SM124 monochrome monitor seems out of adjustment. In the middle it looks perfectly crisp and clear. However, the further you get towards the ends (left/right margins; top and bottom of screen), the more muddled and blurry the display appears.

Are there internal "pots" that I can tweak in order to correct the display?

I am a novice, but I do not feel like giving the local Atari ripoff-dealer $100 to do something I can do myself using a little caution, etc.

What should I do: Use a plastic screwdriver?? Help?? Never done this before. Not even taken apart a TV!
Thanks,
(email or post to net is fine)

1156. 2.5meg STe

Newsgroup: comp.sys.atari.st.tech
Date: 1991-01-24 22:36:58 UTC
From: ekrimen@ecst.csuchico.edu
Message-ID: <1991Jan24.223658.8241@ecst.csuchico.edu>
Source record: 49354

Today I received two 1-meg SIMMs. $88 (including shipping and handling and VISA surcharge) was the cheapest I could find. I got them from Peripheral Outlet (800-332-6581).

Anyway, so I pop open my STe. (Actually, those who've done it know it's not just 'popping' it open. :^) I pulled out the four 256K SIMMs and installed the two 1-meg SIMMs. One of them I put in the slot closest to the rear of the machine and the second, I put in the third slot from the rear of the machine. I closed the hatch, booted up, and, as John Madden would say, "BOOM! Two megs!" Being the inquisitive type, I wanted to see if I could get 2.5 megs using two of the 256K SIMMs I had left over. It's a good thing I didn't replace any of the screws. I've heard that this can't be done (mixing the SIMMs, not replacing the screws :^), but someone on here a couple of months ago said he did, and he didn't use SIMMFIX.PRG. (When SIMMFIX is loaded, it reprograms the MMU and sets _memtop.)

I popped open my STe again and installed the 256K SIMMs in the empty slots. The docs to SIMMFIX say that the machine would stay in a continuous reset-reboot cycle because TOS 1.6 doesn't program the MMU correctly and "any non-trivial programs (e.g. GEM)" will cause the crash. Without SIMMFIX installed, I turned on my STe and everything was fine. GEM was there including some desk accessories and TSRs. I checked amount of free RAM with several utilities and it said that I had 4 megs. I was kinda expecting this, so I wasn't surprised. I then tried memory test programs. One wouldn't load at all. The AERCO tester gave me a <Sense $25> error and had trouble reading the hard drive AFTER I hit any key to start the memory test. I thought this was kinda strange 'cause it's supposed to check RAM not the hard drive. Another one from New World Software lets me configure how much RAM I want to test. So I tried 2.5 megs and I stopped it after it had gone through 2 successful tests. Then I set it to 4 megs and I didn't get ANY errors. I knew that was the wrong one to use.

So I loaded a bunch of memory hogs. It's pretty easy filling a meg, but I never would imagine how difficult it would be trying to fill 4megs. I loaded a ton of stuff and I could tell that it had passed 2.5megs because garbage started being written to the screen and then it crashed and locked up.

In any case, it seems that my machine is working fine with 2.5megs, but all the free RAM indicators are telling me how much free RAM I have out of 4megs. Does anyone know of a program I can put in the AUTO folder that sets _memtop to 2.5 megs, without having to reboot like SIMMFIX?

Thanks for the help.

Alright! I have a serial MS mouse that needs this conversion. Please do
post a follow-up to this, and I would be more than happy to pay you to
send me a Polaroid of the mouse insides after the mod. I could then
digitize it, or draw up a .PI3 file which shows how to do it (which I
would then put on atari.archive). Thanks in advance!

Hi Mickey,
Prospero sells a Resource Construction program in their Toolkit,
which also includes an assembler. Actually, the RCP is just
K-resource, which is quite good and you could get from either prospero
or Kuma.

Any RCP will work. Someone posted one here which is quite good (since
the author included virtually all my suggestions 8^)) Sorry, I forgot
the name of both the author and the program 8^(but you should be able
to find it. It doesn't have the image editing ability, but otherwise
should be able to do everything you need. It's also the best resource
editor to use if you want to compile your resource into your program.
(which people in Europe probably hate, but its the best way to go
in desk accessories.)

cheers,
-sam

1161. Microsoft mouse and the ST

Newsgroup: comp.sys.atari.st.tech
Date: 1991-01-25 06:03:23 UTC
From: <>
Message-ID: <11539@darkstar.ucsc.edu>
Source record: 49353

I have a slight problem here. Just recently, my mouse went the way of the dinosaurs and I don't really have the money to buy a new one right now. (It sucks being a starving student.) I remembered that someone had said that the old Microsoft mouses were compatible with the ST's mouse so I chopped off the female end of my mouse and put it on the Microsoft one, since it originally had a male end. I hooked all of the wires up (except the red one, I believe it is a 5V supply for the Atari mouse but the Microsoft one is a purley mechanical mouse, not opti-mechanical) and it works almost perfectly, except that occasionally it makes jumps on the screen when I use it. It is like there is some voltage or current jump or something going on (I don't really know how they work.) Anyway, I was wondering if anyone else had ever had any problems like this or had any reccomendations for a solution because I would really like to have a steady mouse to use. I thought of putting some capacitors accross the UP/DOWN and the ground. Does anyone know if this would eliminate spikes, given the correct farad capacitor, like is used for decoupling capcitors in circuits? Any help would be greatly appreciated. Thank you.

1162. problems changing resolutions

Newsgroup: comp.sys.atari.st.tech
Date: 1991-01-25 07:35:06 UTC
From: cliff@jarthur.Claremont.EDU
Message-ID: <10473@jarthur.Claremont.EDU>
Source record: 49345

I have problems changing resolution. I have a Mega 2 with TOS 1.4, Quick ST 2.0, DC Desktop (the original, not the newest version), the Rainbow Utilities, and some other things of pretty much no importance, installed. I also have an ICD Hard Drive with the ICD handler software.

Here's the problem: Right after I boot up (I boot up in med res.) and I try to change to low res with the set preferences menu, my computer has a very high tendency to clear the screen and lock up; there's a cursor on the screen and the keyboard reset won't work. My computer changes resolution better if I run a program first after booting up, but that doesn't always help. I've tried disabling some of my programs to isolate the problem, but didn't really have any luck unless my AUTO/ folder were pretty much empty of .prg's.

My computer's fine if I change resolutions manually, i.e. make a SetScreen() call myself, but of course GEM gets confused.

Also, I have the same problems going from low res. to med res.

Any help? Sorry for the long, rambling letter.

Making this work is up to the program you are Pexecing. Programs compiled with the Megamax C will work with both in and out redir.

>i have written a tiny shell, invoked by my cc(1) to start the various passes
>of alcyon, which normally cannot be redirected by gulam. i can mail it to
>u if u want.

I too have written a shell which all but tiny. The ttp is 125K, the sources should be about 10000 lines of C code. Is has ca 100 internal commands. Of your suggested features, it has:

> 1) pipes are a must, i.e. "ls -l | grep xxx | wc -l"

Yeah. Right this line should work: count all lines of a long file list that contain xxx.

> 2) args in quoted strings include spaces, i.e. grep "a string" file
> passes "a string" as a single arg to grep, with an imbedded space

Yeah too. You can also use single quotes to avoid variable substitution etc.

> 3) make it portable

Sorry, it isn't. It uses AES, GEMDOS and [X]BIOS plus some system adresses (0x400 onward) in direct access. However, it is C so if you dispense with some features the rest should be portable.

> 4) support MiNT (and add job control, if possible)

It is outlayed to support Mint (can read out the process table etc) but does not fully support job control. It will as soon as Mint supports the Micro Emacs Editor!!!!!

> 5) RELEASE SOUCE CODE!!!! then the rest of us can improve your work
> (and be more productive, since YOU also benefit from these
> improvements)

Source code is available from me. It costs just one pocket calculator.

> 6) personally, i like history accessible via emacs/vi/cursor keys
> a l tcsh/ksh.

History can be accessed with the cursor keys. You can:
press Uparrow and recover the previous command line,
press Ctrl Uparrrow and execute the previous line,
type foo and press Shift Uparrow to recover the last command line
beginning with foo, where foo may contain Unix wildcards (*?[]).

> 7) command prompt should be able to deal with imbedded escapes
> (i.e. ESC p/ESC q for reverse video). gulam gets confused

Yeah. The escape character is the circumflex since the backslash is occupied
by Tos. Example:
echo ^033pThis is inverse^033qthis is not

> 8) make it possible to redirect inside scripts

Yeah, as well.

> 9) make it possible to do things like "sh file" (or, if memory
> serves, "echo 'command' | csh -s")

Yeah.

> 10) loadable common programs (cat, ls, grep, etc) which stay
> in memory (i'd rather have them in /bin, too)

Most common programs (including cat, ls, grep [but not including etc :-)])
are built-in. It is possible to keep binary programs resident and execute
them via shell functions.

> 11) support something like SLASHCHAR env variable, so cmd lines
> can use either "cmd /path/file" or "cmd \path\file". shell
> translates according to SLASHCHAR before exec'ing cmd. it
> would be nice to support alternate device names, e.g. "/dev/c"
> for "c:" in cmd lines and scripts.

You can set a flag which when active translates all slashes to backslash.
It is still possible to use slashes by quoting them.

> 12) soft links would be a definite plus, if u feel ambitious...

Not yet, sorry. Not planned, not considered really useful unless done on
OS level.

Some other features of the program (called the Okami Shell):

Shell functions (=resident scripts), hash table to shorten program search time,
shell varaiables, a built-in RPN calculator with some 80 functions, terminal
emulator, terminal server and many, many things I dont really remember...

In general, it closely resembles the Bourne Shell with most of its specialities (like the type command, $CDPATH, $PATH, export, hashing etc). It's a very solid piece of software. If you find some of the built-in commands unuseful for you, you can get a version without these, thus making the program smaller.

It has only two drawbacks:
1) The documentation (about 200K) is is German. Sorry, but I have no time to translate it. It has however a help file with brief explanations which is in English. Maybe you find somebody who is able to read the German documentation.
2) I do not know how to get it by email. There might be a version in the Fido net, so look in the lists of the German nodes (the city is Aachen, try a mailbox called "Uniline", although I am not sure). A safe way to get the Shell is to send a diskette to the following adress:

Wolfram Roesler
Augustastr. 44-46
5100 Aachen
Germany

(not West-Germany anymore, fortunately) Dont forget a stamped and adressed return envelope. If you want the sources, dont forget the pocket calculator (if you include a Hewlett Packard you will get the following 10 releases of the shell free of charge).

Hope to hear of you!

Greetings to those who prefer Unix to Msdos and a command shell to mousing

wr

> E.g program file WORK.PRG will in fact be two programs
> CHECK.PRG and THIS.PRG

>CHECK.PRG will execute first and then call THIS.PRG.

> I also want to able to remove CHECK.PRG from THIS.PRG and
>seperate the two again.
>--

The required Gemdos function is Pexec to execute another prg. After execution
control is returned to the calling program.
You can also use the AES shell lib functions to call a program while discarding
the caller.
For further details RTFM. When using Pexec, set the last parameter to NULL or 0
instead of "" in order to pass the environment correctly.

BTW, all the world seems to be writing shell programs. But you'll have to do
a lot before you reach up to the Okami Shell, see my posting in atari.st.

1166. Connecting a Fujitsu M2614ESA

Source record: 49361

A friend's computer is having some very odd problems. She just had an early model 520STfm upgraded to 2.5 megs with JRI's simm board and a double sided drive.
When she got it home, whatever she typed was purely random. Nothing would be consistant. [I checked a couple of disks for virus but didn't find any btw] She took it back to the dealer (yeah, we have one! :-) and had him check it out again. Of course it worked fine at the store. She brought it back home and of course it acted up again.
So I come over to calm her down and see what I can do. Through some damn luck, I found that unplugging the Mouse Master would stop the problem. Strange... So I took the computer and the MM back home to try them with my computers. Of course, they have worked flawlessly.
What I am suspecting is one of the joysticks which I know to be sometimes very flaky with the ST. (I don't have it with me to test it). What I am really wondering is why? How?
Could it be a flaky joystick that is sending in all these inputs and confusing the keyboard processor? Might it be a cable under the keyboard that gets pushed when we un/plug the MM? Or does it sound like a virus people know about?

I really appreciate all your help! Either e-mail or posting is fine.

Marshall

- Where can I get some documentation on all the stuff defined in
- DESKTOP.INF file?

Atari.archive.umich.edu. I think the doc is called DESKDOC.ARC.

- Maybe somebody can help me with what I want do do:
-
- I want to replace the [show] selection, but not the [print], when
- double-clicking a non-executable file with QVIEW.PRG that came with
- QUICKST package. Can this be done with DESKTOP.INF file?

Select QVIEW.PRG once (highlight it) from the desktop. Go to the options menu and select Install Application. Then save desktop. If you don't have Rainbow TOS, load DESKTOP.INF and add the pathname to QVIEW.PRG at the bottom of the file. In fact, doesn't the QuickST manual tell you how to do this?! BTW, this will replace both the show and print selection. You will need a print utility to replace the print selection.

If you get DCShowit, I think it will replace only the show selection. It can be found at atari.archive.

Yes; just doing "bg -o aux: shell <aux:" should start up a shell connected
to the RS232 port (replace "shell" by whatever shell you prefer; bash or
init.prg should work reasonably well). Note that you should use the
bg program because it sets up the control terminal properly; just running
the shell in the background with "&" won't do this.

1177. new gnulib in assembler for gcc 1.38 available?

Newsgroup: comp.sys.atari.st.tech
Date: 1991-01-27 01:58:44 UTC
From: gl8f@astsun7.astro.Virginia.EDU
Message-ID: <1991Jan27.015844.23554@murdoch.acc.Virginia.EDU>
Source record: 49367

After not saving the latest announcements of gnu-stuff because I wasn't going to install it, a friend suddenly needed it to cross-compile for a robot he's got.

The gcc 1.38 distribution on atari.archive.umich.edu doesn't have a machine-language version of gnulib.c. The file "libsrc" from gcc 1.36 in the atari/gnustuff/tos subdirectory contains something that he's using -- but my question is: is this file up to date? Any bugs? Why doesn't the 1.38 distribution contain a version of gnulib.c that's suitable for cross-compiling? Or are we confused?

Also, where's the "official" 1.38 ftp site at cwru? The machine dsrgsun.ces.cwru.edu doesn't have anything in its ftp area.

Thanks in advance.

Source record: 49368

In article <5651@feldspar23.UUCP> dalessio@motcid.UUCP (Mario D'Alessio) writes:
A friend of mine has an NEC CD-ROM drive he is selling.
I am wondering if I can use it with my ST. I have an
ICD host adapter with an OMTI controller running a
Syquest removable. Can the CD-ROM drive connect to this?
This is odd. The ICD transforms the ACSI-SCSI conversion and the
SQ555 is a standard SCSI-device, so no additional controller
should be needed at all.

Connecting that CD-drive should be no problem as long as it is
a SCSI-drive (which it most likely is)

If I can connect them, will CDs for the ST work in this
drive?
It will mostly be a metter of software. If you buy the CDAR
from Atari you get something called "Metados" which allows you
to access the CD-partitions. You might get the "Scheibenkleister"
book as well and use the software of the disk inside it ;-)

Sorry, I have no specs on the CD-ROM drive to help. If
they are needed, I will get them later.
You might want to check whether there are any oddities in the
SCSI-commands of the CD-drive. As you only can get SCSI-0
commands through the DMA-port, these won't hurt, though...

Greetings,
RIPLEY

Disclaimer: I don't have the book handy at the moment to look
the information up.

In comp.sys.atari.st.tech you write:

>Hi !!

> I am interested in knowing the relative strengths of TurboST and
>QuickST II. Please help me.

Hi!

From my point of view there is not much difference between TURBOST
and QUICKST. QUICKST is a little bit faster, but only a little!

QUICKST is a programme, TURBOST a accessory which can be stopped at
each time. Maybe you will need this if you don't have CON_FIX of
Karsten Isakovic which corrects a little incompartibility of both!

I hope, this will help you

Uwe

P.S. Have you seen NEWVDI yet? It should be the best solution!

Hey wooow, I would get a priest right away guy. This system is obviously posessed.

But, seriously, make sure the joystick is electrically contact NEATURAL, that is, it isn't leaning in anyway, and the fire button is not depressed or shorted when you turn the machine one. Your ST doesn't like to be informed that your playing a game while its trying to boot up, it thinks your being a prude, and can get quite angry.

1189. Squeeky monitor..

Newsgroup: comp.sys.atari.st.tech
Date: 1991-01-28 21:04:07 UTC
From: petercl@castle.ed.ac.uk
Message-ID: <8121@castle.ed.ac.uk>
Source record: 49382

Hello,

I have a problem with my SM124 monitor. It emits a high pitched
squeek from around the on/off/volume switch that starts about 5 mins
after I have switched it on. The squeek is very loud and annoying.
Smacking it one tends to help for a bit but this only keeps it quiet for
a few minutes. Has anyone else had this problem and does anyone know how
to fix it? I have considered taking it apart and having a look but I'm
not too hot on the inside of monitors.
If anyone has got any suggestions then either mail them to me or
stick them up here. Thanks.

> Hi !!
>
> I am interested in knowing the relative strengths of TurboST and
> QuickST II. Please help me.

Well, I got out Quick Index and did a little test. Here's the results:

(This was run on a 1 meg 1040ST with TOS 1.4 on a mono monitor)

Neither Quick ST 2.1 Turbo ST 1.8
TOS Text 100% 327% 315%
TOS String 100% 1304% 1255%
TOS Scroll 100% 134% 133%
GEM Dialog 100% 284% 235%

Memory Usage: 0K 23.7K 53.1K

I've been using Quick ST II for a couple of months now, and haven't run into a single problem. (And with the CONS_FIX prg, I can run .TOS and .TTP in the Gemini Console window.)

Quick ST is also cheaper, and you get a few goodies with it. (QINDEX.PRG, the desktop customizer prg....)

From: Bob_BobR_Retelle@cup.portal.com
Message-ID: <38584@cup.portal.com>
Source record: 49381

Mike Fields asks:
>I have seen mention of a program called SIMMFIX. What does this do
>and do I need it to use my 4 Meg.???

SIMMFIX is only needed when you're using a combination of 1 Meg SIMMs and
256K SIMMs for a total of 2.5 Megs.

With your 4 Meg STe, you won't need anything like this.. just boot up and go!

Source record: 49380

---
quick question:

if i Pexec a process, then within that process do a Dsetpath/Dsetdrv,
when i return from the Pexec, will the parent think it is back in the
same dir before the Pexec, or will the child's actions be
propagated back to the parent? in other words, is GEMDOS's concept
of current/default directory global in scope or is it per process?

if per process, where is this information stored?

reply via email, unless u feel this has more wide ranging interest...

thanx a priori.

I replaced the (Adaptec+Tandon)-combo in my SH204 by a ST1096N about a year
ago, using Claus's Software from his 'Scheibenkleister' book. Apart from a
minor problem during cold booting (which does not hassle me enough to really
enquire what exactly it is :-) it works like a charms, 80 MB and noticably
faster than before. [I just bought the Seagate drive, plugged it in, attached
it with some metal rods - its much smaller than the old one - and partitioned
it. I did this because the old drive had suddenly died ...]

So does mine (amongst other things) but it increases in pitch after
a few minutes then dies away. Its not that much of a problem but I'd
like to get rid of it.

Anyone else had problems with these monitors?

NEWVDI is a new VDI (compare with its name!) including GDOS. It is written
in 100% assembler. And of this reason it is very fast, expecially with
KAOS-TOS 1.4.
Maybe both is not available in United States. Here in germany NEWVDI is
distributed by BELA.

Why don't you try it? The answer is that it's per-process. The
information is stored partly internally in GEMDOS and partly in the
process' basepage (in the GEMDOS-private part).

(Sorry if this is a repost - Trouble locally with rn/pnews)

Hello,
I would like to use the mouse in a TOS program, ie to be able to get the x and y coordinate of the mouse and the state of the two buttons. I have seen the 'xbios #0 initmous' call that sets up (among other things) an address of a routine to handle the mouse input. What I would like to know is how to program this routine, ie how to read the mouse packets. (Also how to reset the mouse to its previous state on program exit). Any help would be appreciated.

Also, please could someone recommend a good book on the 'internal workings' of the ST, such as the low-level stuff like the above, keyboard reading, detailed description of linea, etc. I have the book "Concise Atari ST 68000 Programmers Reference Guide" which contains many things, but not always very accurately or to great detail.

Thanks,
Andrew

>the ST, just so I could be running a shell?

Well, sure you could use the 400 as a terminal for a Unix-like system. But that doesn't make it a *good* idea. The problem with the 400 is that you won't have a clearly legible 80 * 24 character screen. When you use advanced OS's and especially if you want to do development work, you'll want at the very least an 80 * 24 screen. You can play with the 400 as a terminal, but you'll soon tire of the inconvenience.

If you have the money lying around, a used 520STm with a VT100 cartridge would be a wonderful choice for a terminal. Otherwise, as far as the 8 bit machines are concerned, my own favorite approach would be a Radio Shack Color Computer 3, which has an 80 * 24 capability (640 * 200 resolution) and RGB, RF and composite outputs built in. And, of course, a version of OS-9 available.

Well I don't know if it's the same problem as on my MacPlus, but a high pitched tone means the flyback transformer is going. I also have an SM124 on my 1040 which does the same thing, not quite as bad as when the Mac would whine. It might be worth taking it in to see if that's what it is. It might not be too expensive if the part is readily available (ha.). If mine starts bugging me too much I might.

It's per process (unlike MSDOS, where it's global).

> if per process, where is this information stored?

Presumably, either in the basepage or on the stack. In MiNT, it's stored in the process structure. In either case, trying to manipulate it is highly non-portable and virtually guaranteed to break on some future version of TOS/MiNT, not to mention RTX or MX2.

>djw@hpldsla.hp.com

I wanted an STe sound player too, so I wrote 'eplay', it is at atari.archive
as /atari/sound/players/eplay20.arc and it only works on the STe!
It is a "command line" type program (no GEM), so you can have it execute in
an auto shell script on bootup, to either play a sound, adjust bass/treble/
master,left,right volume and other stuff...

I used info posted to the net a while ago about the DMA soundchip to make it,
and I don't know if the info is posted anywhere, along with the other info
that was around like the 4096 colors and new ports ones..

If noone knows where this info is on the net, then I will compile the info
I was given and send it to atari.archive.

>if I have just forced it to be included with the compiled code.

Why put them in the DA? I think this is being a bit presumptuous of you...
How do you like it when you get software with a German RSC? At least with
a resource file you can change it. And on this point, I wish people would
stop using form_alert(2,"[Are you sure?][Yes|No]"), rather than a free
string, or Resource Alert from a .RSC file. Human-Language dependent
programs are a bit rude, especially on a system that has heaps of
European support... ANYWAY...

> Any tips on writing D.A.s is very useful as I have seen no documention
>on how to write them.

Have you written a GEM program? DA's are similar...

Do you initialisation:
(if "initialisation" was in a .RSC, you could change it to initialization)

1. Get your appl id (using appl_init, as for a GEM program)
2. Register the name of your application (use menu_register)
3. Load your RSC (use rsrc_load)
4. Whatever else you want (create buffers, etc.)

Then:

while (1)
{
get an event (using event_multi, or event_msg)

if the event is an AC_OPEN, do whatever you want to do.
}

Basically, it is a GEM program + menu_register + AC_OPEN handling,
so you should be able to convert a GEM program pretty well. One note
though, I don't think DA's are given access to keyboard events, so
you may have to circumvent this somehow. (Any clues?)

WARNING:
I am a Modula-2 programmer, and my FTL M2 compiler, or my memory
may cause slight differences from the normal identifiers.

Can anyone figure out why the a is not equal to b in the following
program? And why the length of "test" is 3? I'm using LaserC.
In other words how do I really get into binary mode (no translations).

Thanks in advance,
Eric

```
#include <fcntl.h>

/*
test contains:
00000000 000d 0a ...
*/
main()
{
char *name = "test";
int fd;
short a = 10, b;

unlink(name);
fd = creat(name, O_BINARY);
if (fd > 0) {
write(fd, &a, sizeof(a));
close(fd);
fd = open(name, O_RDONLY | O_BINARY);
if (fd > 0) {
read(fd, &b, sizeof(b));
printf("a %d, b %d\n", a, b);
} else {
printf("couldn't reopen '%s'\n", name);
}
} else {
printf("couldn't open '%s'\n", name);
}
}
```

Well, sure you could use the 400 as a terminal for a Unix-like
system. But that doesn't make it a *good* idea. The problem with
the 400 is that you won't have a clearly legible 80 * 24 character
screen. When you use advanced OS's and especially if you want
to do development work, you'll want at the very least an 80 * 24
screen. You can play with the 400 as a terminal, but you'll soon
tire of the inconvenience.
What I can imagine perfectly well is using a cheap 8bit-machine to
be used as a console for certain systems, so you can use your other
terminal(s) for better things than logging system messages.

1219. profiling MWC v3 code

Newsgroup: comp.sys.atari.st.tech
Date: 1991-01-31 23:44:48 UTC
From: rossj@cognos.UUCP
Message-ID: <9277@cognos.UUCP>
Source record: 49262

I recently posted asking if anyone was aware of a profiler for MWC v3. With no response, I still needed to profile some code. This short program, compiled under version 3, regresses a v3 binary back to v2. You can then use David Rowley's profiler on it.

This was all done by experimentation, so I don't know if I'm performing the conversion correctly. If anybody improves it, please let me know.

The program doesn't check to see that you're actually converting a v3 binary, so use it with caution (convert a backup). You can verify that the conversion worked with the 'file' command.

```
#include <stdio.h>
#include <gemout.h>
#include <nout.h>
#include <canon.h>

char buffer[32000];
char other_crap[32000];

main(argc,argv)
int argc;
char *argv[];
{
FILE *in;
struct gemohdr gem_head;
long where_to;
struct ldheader ld_head;
int table_size;
int crap_size;
int i;

if (argc < 2) {
fprintf(stderr,"usage -- v3tov2 <executable>\n");
exit(-1);
}
printf("Opening %s.\n",argv[1]);
in = fopen(argv[1],"rwb");
printf("Reading header.\n");
if (fread(&gem_head,sizeof gem_head, 1, in) != 1) {
fprintf(stderr,"Couldn't read input file.\n");
exit(-1);
}
if (gem_head.g_magic != GEMOMAGIC) {
fprintf(stderr,"Not an executable file.\n");
```

```
exit(-1);
}
printf("Text segment=%7ld bytes\n",gem_head.g_ssize[0]);
printf("Data segment=%7ld bytes\n",gem_head.g_ssize[1]);
printf("Bss segment=%7ld bytes\n",gem_head.g_ssize[2]);
printf("Sym segment=%7ld bytes\n",gem_head.g_ssize[3]);
where_to = (long)(sizeof gem_head) +
gem_head.g_ssize[0] +
gem_head.g_ssize[1];
printf("Seeking symbol table at %ld.\n",where_to);
fseek(in,where_to,0);
printf("Reading link header.\n");
if (fread(&ld_head,sizeof ld_head,1,in) != 1) {
fprintf(stderr,"Couldn't read link header.\n");
exit(-1);
}
if (canshort(ld_head.l_magic) != L_MAGIC) {
fprintf(stderr,"Didn't find link header magic number.\n");
/* exit(-1); */
}
printf("Reading symbol table.\n");
table_size = fread(buffer,1,(int)canlong(ld_head.l_ssize[L_SYM]),in);
printf("Symbol table is %d bytes long.\n",table_size);
printf("Reading trailer.\n");
crap_size = fread(other_crap,1,32000,in);
printf("There were %d bytes of trailer.\n",crap_size);
fseek(in,where_to,0);
fwrite(other_crap,1,crap_size,in);

ld_head.l_magic = canshort(ld_head.l_magic);
ld_head.l_flag = canshort(ld_head.l_flag);
ld_head.l_machine = canshort(ld_head.l_machine);
ld_head.l_tbase = canshort(ld_head.l_tbase);
for (i = 0; i < NLSEG; i++)
ld_head.l_ssize[i] = canlong(ld_head.l_ssize[i]);
ld_head.l_entry = canlong(ld_head.l_entry);

fwrite(&ld_head,sizeof ld_head,1,in);
fwrite(buffer,1,table_size,in);
printf("Changing GEM header.\n");
gem_head.g_ssize[GO_SYM] = 0L;
rewind(in);
if (fwrite(&gem_head,sizeof gem_head, 1, in) != 1) {

Which is just as well ! Who wants 256 colour sprites???? Can you imagine
how SLOW it would be to draw up a sprite if you HAD to set all bitplanes?

One common way for Fast Raster Routines (ie. the subject line), is not to
draw on all bitplanes. That is why we have them that way.

Perhaps Michael has too many fond memories of 8 bit Ataris, when you only
had 2 bits per colour index anyway, so it didn't matter.

I imagine there is also a hardware concern that places bitplanes as they
are too, if anyone could expound?

>how SLOW it would be to draw up a sprite if you HAD to set all bitplanes?

Actually, if 1 pixel = 1 byte it would be much faster to draw a 256
color sprite.

TT video memory is set up like this:
(note: I guess this is the way it's set up based on the
information above...)

| 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 |

8 words make 16 pixels, each word is a bitplane.

Pixel 0 is made by taking the 15th bit from each bitplane.
Pixel 1 is made by taking the 14th bit from each bitplane.
etc....

With the memory set up this way to set a pixel requires
8 instructions (BSETs or BCLRs in some combination)

To move a raster to the screen would require a lot of:
ANDs,ORs,LSRs, & MOVEs

If TT video memory was set up so 1 pixel = 1 byte:

To set a pixel would require:
1 MOVE

To move a raster to the screen would require a lot of:
MOVEs (Could be combined into some MOVEMs)

>One common way for Fast Raster Routines (ie. the subject line), is not to

8 bit graphics were not very fast either because you had to
do ANDs, ORs, RORs to get your 2 bits to the right place.

>
>I imagine there is also a hardware concern that places bitplanes as they

>You also can't set the volume-label bit or any of the undefined bits.

Now that we are talking about the undefined flags, what exactly do they do?
I remember setting them on a ramdisk file with the result of making that file
disappear, so I didnt do much more experiments about that.
Is it possible for applications to use these flags in a 'self defined' way?

BTW: why is it not possible to hide a folder? Just to keep people from turning
files to folders by changing a flag? How about making a folder readonly, which
would affect all of its files?

If the mouse is a bus mouse, all you need to do is build a connector.
If the mouse is a serial mouse, more work is involved. The guts of
the mouse that converts the output from the sensors to serial data
need to be bypassed. This is the situation I am in and someone is
going to try to help me do this. If I am successful, I will post
some information to the net.

If you have the bus mouse, here is the message that was posted by
someone else on building the connector. Good luck.

----------------- BEGIN INCLUDED MESSAGE ---------------------

Well, here is how to connect a Microsoft Mouse to an Atari ST. (520/1040)
The Atari has a 9-pin D-type connector. The Microsoft Mouse has a rather
strange connector on the end. To prevent having to cut the mouse cable up,
I made this adaptor. If you still can't follow it, please let me know and
I'll try to redescribe it. This does work for me. I've been using it for
6 or so months now [Note, it's been 2 years now!] with no problems at all.
It does take some soldering skills, so if you're not so hot at soldering,
find a friend to help.

As far as I know, this does not effect your Atari's warranty. However, I
have not asked Atari.

Atari ST Microsoft Mouse ST expected signal
----- -- --------- ----- -- -------- ------
1 5 XB
2 3 XA
3 8 YA
4 9 YB
5 N/C N/C
6 2 Left button
7 N/C +5VDC (N/C)
8* 6 and also tie to pin 1 Ground
9 7 Right button

* = I am not sure why I have pins 6 & 1 tied together, but it does work.

The Microsoft mouse connector looks like this. This is the solder side,
with the leads pointing up.

```
---------------
| 1 |
| 2 3 4 5 |
| 6 7 8 9 10 |
| |
---------------
```

If you can not use the connector, the pins are numbered as follows. This
is the connector side from the Microsoft Mouse plug:

```
/------------\ This is a view at the front of the connector.
/ Blank "KEY" \ It is where the plug from the mouse would be.
/----------------\ The pin labeled 'n' is not connected.
| n 4 X 8 | The place labeled 'X' is filled, and does not
| 9 7 1 2 | have a pin.
| 5 6 |

1225. dying? 1040ST

Newsgroup: comp.sys.atari.st.tech
Date: 1991-02-01 16:53:09 UTC
From: wchow@world.std.com
Message-ID: <1991Feb1.165309.13322@world.std.com>
Source record: 49264

this sounds like the right place to ask this...

after acquiring a syquest drive i started moving my ST around
generally rearranging stuff to accomodate the new drive.

i tried using icd's ratehd and idcheck to check out the sysquest
and that seems to lock up the syquest. after rebooting several times
i could no longer autoboot from my seagate scsi=0, but i could still
boot from the floppy. running icdboot from a floppy now
again locks up the syquest (amber/orange led on). so i reboot
and retry several times. now i can't even boot up on either
floppy or hard drive most of the time.

symptoms: when i do get the screen i get halfway thru the auto folder
and then get 2/4 bombs, sometimes i turn on the ST and only the powr
light comes on but everything else stays silent (floppy,monitor)

can someone nudge me towards the possible solutions to this?

oh yes, i have a datafree memory board that brings me up to 4 megs
and yes everything was working fine till the latest attempt at
rearrangement of my ST setup.

.

1226. Using GDB

Newsgroup: comp.sys.atari.st.tech
Date: 1991-02-01 17:08:26 UTC
From: dinapoli@rodan.acs.syr.edu
Message-ID: <1991Feb1.170826.791@rodan.acs.syr.edu>
Source record: 49267
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

Howdy! I've been having a problem getting GDB to work on my MEGA 4.

If I compile with the -gg switch, the resulting symbol files cause
gdb to crash when I attempt to load them.

If I compile with the -g switch I get the following error message when
I attempt to link the executable...

Bogon alert! wrote 213 symbols, expected to write 235

I'm not sure about those numbers, but that was the general error message.
the executable is produced, and the symbol file created with sym_ld does
load properly into gdb. But when I attepmt to run the executable from gdb,
I get "Program terminated with code #ffffff95" (again, not sure of the
number).

Does anyone know how to create good symbol files and good executables???
I can't use the -mshort flag because I need to have 32-bit ints (if that
makes a difference).

thanks for your help!

Ron D.

1230. 32,768 color upgrade to Mega and having problems

Newsgroup: comp.sys.atari.st.tech
Date: 1991-02-01 22:17:49 UTC
From: cliff@jarthur.Claremont.EDU
Message-ID: <10611@jarthur.Claremont.EDU>
Source record: 49265

I was thinking of performing Mr. Barry Orlando's 32768 color upgrade on my Mega ST2 (Motherboard Rev. .5.0) and the chip I found is not the Shifter chip he says I'd need. He lists part number: C025914-38A.

I have what I think is a Shifter chip, but he part number on the chip, which I pulled from a newish 1040ST (it came with Mega TOS) is:

C07013-002
(C)ATARI 1987
-31 I10356-01
8821KRR

Am I totally hosed?

Also, he says (in the text file posted a while ago) if my RAM chips were slower than 120 nanoseconds, then I'd have to do something else. The chips in my computer are: M411024HP
-15C*(M) AT&T
11187 74
Does anyone know what speed they are?

One more thing, Mr. Orlando says:
"Three wires are installed from the color board to three vias (trace thru holes) located nearby on the motherboard."

What is he talking about? I didn't see anything like that at all in the 1040ST. Is there anything equivalent I should be aware of in doing this on my Mega 2?

Will I have to do anything truly different in this upgrade compared to doing it to a 1040ST? Please let me know.

1231. GFA-Basic 3.5E Question

Newsgroup: comp.sys.atari.st.tech
Date: 1991-02-01 22:19:29 UTC
From: tar@naucse.cse.nau.edu
Message-ID: <3264@naucse.cse.nau.edu>
Source record: 49271

Does anybody out in Netland know how to change the format in GFA-Basic's
DATE$ function from European to U.S?

Thanks in advance for any help provided.

Regards,

1232. Questions (new to the atari, have a TT)

Newsgroup: comp.sys.atari.st.tech
Date: 1991-02-02 00:46:47 UTC
From: rodent@netcom.UUCP
Message-ID: <22533@netcom.UUCP>
Source record: 49272

I'm coming from a heavily Amiga/Unix background, trying to get used
to developing with Mark Williams on a top-of-the-line TT.

My first problem was the apparent lack of a decent shell or editor.
After studying the docs for "MSH" it seems it MIGHT be adaquate,
but the editor is hopelessly primitive (a uEmacs with a worse user
interface than the pathetic thing Commodore's been bundling for years)

I assume there are serious editors out there, that support mice and
undo and can reconfigure the keyboard etc. like CygnusEd Pro for the
Amiga or Emacs for the Unix world. Can someone give me a tip?
What do Serious developers use? Price is not a concern.

I also sorely need a ramdisk facility of some sort - I've talked to
atarioids who say they have them, so I assume it's not difficult.
With 6 meg to kill, and a DOS that Really Thrashes the hard disk,
I *need* a ramdisk.

Finally, is there a way to turn off that horrible beeping every time
I press a key? I shall go insane listening to it much longer.

Thanks. Be nice and you'll win a convert to Atariness. My development
setup on the loaded Amiga3000 that sits next to the TT on my desk is
wonderful, but that's because of years of accumulating the best utilities
from all sources. This is what I'm looking for on the TT.

Ben Discoe, computer scientist/deep ecologist.

Hi Dave, I posted source to the atari sources group awhile ago called DUBL_VIS that is a disk formatter that runs as a program or an accessory. You should be able to get it from an archive server (although I haven't looked for it myself...)

That program also has its resource built into the source code, so it can show you how to use this trick.

What compiler are you using? and what program are you using to get your resource into source code form? Many compilers require a different startup routine linked in to compile a resource file. Accessory startup code for the Sozobon compiler was posted here about a month ago, its called SOZOINIT.

Mail me if this is still totally confusing...

>How do you like it when you get software with a German RSC? At least with
>a resource file you can change it.

Gem has some bugs with memory management - If a resource file is loaded in,
that memory is lost every time you change resolution. If 3 DAs have 10K
resource apiece, you lose 30K of memory every time you change resolution. Ack!

Besides, old Tos versions can only safely Malloc() between 20 and 40 blocks
of memory, and each DA that loads a resource Mallocs one of those blocks
away, increasing the Malloc risk for the main program. For these reasons,
DA's should build in their resources.

Arrrgh, Warwick !!
The Bitplane arrangement in the ST is lousy for software ops there is no reason to set up more than one plane for some operations whether the planes are interleaved or not. The arrangement in the ST is the result of some very simple DMA hardware which is used to read the video memory.

>
> One common way for Fast Raster Routines (ie. the subject line), is not to
> draw on all bitplanes. That is why we have them that way.

See above: The ST way is slow for software no matter how many planes you want to draw on. Only the IBM PC is worse.
>
> Perhaps Michael has too many fond memories of 8 bit Ataris, when you only
> had 2 bits per colour index anyway, so it didn't matter.
>
> I imagine there is also a hardware concern that places bitplanes as they
> are too, if anyone could expound?
> --

Ok. Ill have a go (Did you expect anything less ?)

This is guess work but from an engineering point of view this is probably what happens.

The Video memory is arranged in words, the same pixel from one two or four successive words are used to form the index into the clut (Colour lookup table). The reason for doing this is pretty obvious, since we have 3 modes it is simpler to read n words and always combine the bits in the same way

than to combine successive 1 2 or 4 bits within words differently between modes as on a PC thus in low rez the state machine loads 4 registers with memory values. At each video clock interval each of the location is shifted once (left I think) and a bit falls of the end of each register which are combined in a 1,2,4,8 type way and used to index the clut. In Med then only two fetches are done to register val one and 2 and 4 and 8 are left cleared (twice as fast of course) the lower two bits of the 4 bit index then is only significant. In high rez only one register is loaded 4 times as fast (well thats the theory although mono timing is different)

All this makes mode switching little more than a counter and a couple of decoders, pretty trivial really. Note that the DMA machine then is not required to permutate its counting in order to access different memory regions (Which is all that would really be required to have logically distinct planes) In fact separate bitplanes probably would be trivial al that would be required is to use (Programably) the 2 highest bits b15 and b14 in the dma counter as the LSBs on the bus and just b15 in med (of couse this means shifting all the address lines down by a bit to change modes :-)

Of course now somebody at Atari will probably send me a big flame
and tell me that things are actually different, but do I care ??? No
This fits the model and will do for me :-)

1236. PCDITTO2 Fix

Newsgroup: comp.sys.atari.st.tech
Date: 1991-02-02 05:39:09 UTC
From: marshall@batserver.cs.uq.oz.au
Message-ID: <7139@uqcspe.cs.uq.oz.au>
Source record: 49276
Cross-posted to: comp.sys.atari.st.tech,comp.sys.atari.st

I had a problem with PCDITTO2 (and PCD1), which is now fixed.
PCD2 ran OK, except it would not recognise the hard disk.
My H/d is a Megafile 20, with 2 partitions: C 14Meg, and D 6 Meg.
Mostly I use D for PC stuff.
PCD ran programs from floppy with no complaint, and allowed me to change
directory to C or D. But when I tried to run something - say "dir", from
C: or D: it gave the message "Divide overflow". Likewise if I tried to
access the hard disk while in an A: directory.
After much blood, sweat, and tears, and backups and reformats and
repartitionings and backup restores I fixed it, as follows.
The Mgafile manual advises that the Megafile 20 should be treated as an
SH205. PCDITTO2 AHDFIX says that it should be applied (AHDFIX.PRG, that is)
to SH204 only. Eventually I ran HDX to remove and then install the H/D
driver, and IMMEDIATELY after quitting HDX, ran AHDFIX. That did the trick!
I had tried, once before, in desperation, to run AHDFIX, but I hadn't
realised that it MUST be run IMMEDIATELY after running HDX or any of the
zeroing or partitioning or formatting processes.
BTW: PCD2 runs every PC program I have tried so far:
in particular: MSWORD, QUATTRO, QED, TurboPascal, all the compressor/archivers, Fastback,
and many others.
But there are now much better PC emulators around.
Hope all this helps.

neil@cs.hw.ac.uk (Neil Forsyth) writes:

> Wouldn't it be a nice idea if Atari were to assign a desktop info file
> entry to application use.

> eg. #+ APID PR#1 PR#2 ...

This works, eg. if you add such a line with a text editor, you'll get
it back correctly with shel_get() and some search effort in the buffer.
The DeskTop keeps your added-on lines even when you use "Save Desktop".

But BEWARE: If you add these lines at the top of the DESKTOP.INF, you'll
get a really nice crash, because the control panel assumes that it's info
lines are located immediately at the beginning of the DeskTop buffer.

Daniel

P.S.: I know of sb. who implemented the "#Z" line on TOS < 1.4 systems by
installing a little resident prog getting this line and doing some auto-
start stuff. (With nice results on 1.4 machines... :-)

A video scheme that would have been really nice and fast would have been to have each bitplane in a contiguous segment of memory. Granted, the hardware and the memory fetching scheme would be more complex than the current one. But with this scheme, it would be possible to design with some kind of inherent upgradability (to increase bitplanes). Writing raster routines would also be more intuitive.

Yes. Use the mode 1 command.

I found that my USA version of the interpreter defaults to mode 1 while the
USA version of the compiler defaults to mode 0. If you explicity put the
Mode 1 command in your program, both the intepreter and compiler will
act consistenly.

Mode 0, therefore, selects European date format while Mode 1 selects USA
format.

> of current/default directory global in scope or is it per process?

All these informations are process-dependant.

> if per process, where is this information stored?

The basepage contains information about the current drive, the redirection state and a list of "path handles" (one for every drive). When a new path is used, a slot in the internal path list is allocated and the path is stored here. TOS now accesses the directory via a handle. When you select a path with Dsetpath(), such a handle is locked permanently (till the process terminates or another Dsetpath() is used). Other handles are only allocated temporarily.

TOS may manage a maximum of 40 path handles, beware when using a lot of logical drives (eg. many small partitions on your HD). When a new process is started, all path handles are copies from the parent basepage and the usage counters in the dir handle pool are incremented. At the first change of the path a split-up is made, i. e. a new entry in the pathtab is allocated.

(... and so on :-)

> reply via email, unless u feel this has more wide ranging interest...

I think it's a quite interesting thing, BTW: Does anybody know how to expand the dir handle list? Programs like FOLDRnnn.PRG only solve the memory management problem, not the problems resulting from the limitation of the path pool.

Daniel

>it a TSR or desk accessory?

The NewVDI (right called NVDI) costs in Germany DM 99,- I think that
must be about $65 US.

It is a Program wich you place in the AUTO-Folder. You can counfigur it.
For example you can say do you want to use the GDOS part of it (for
programs wich couldn't work with GDOS switch it off).
With NVDI you can install a Systemfont compatible Font (8x16) as System-Font.
So all Programs use it.

The program comes with a manual describing the useing of GDOS.

I bought NVDI and wouldn't miss it :-))

The squeek is coming from your high voltage 'flyback' coil. A lot of monitors do this and it is generally a
sign of impending failure. (although it may be years before this happens...) The best thing you can do
is live with it as the price/pain of replacing said coil is probably not worth the trouble.

Thanks for the info, John. In mild browsing of my GFA-Manual I never did manage to find out how to do that (under the description for DATE$, TIME$, etc. it doesn't mention HOW to change the format...*SIGH*)

At least now I can use my programs without getting confused about what the date really is.

>>how SLOW it would be to draw up a sprite if you HAD to set all bitplanes?

>Actually, if 1 pixel = 1 byte it would be much faster to draw a 256
>color sprite.

TRUE! BUT IT IS TOTALLY UNREALISTIC TO WANT 256 COLOURS ON
ONE SPRITE!!!!!

With only 4 colours, you often use all colours. With 16, you MIGHT
consider optimising code that only draws on 3 bitplanes. But with a 256
colour system, you would be crazy to use ALL bitplanes in EVERY sprite.
Take the following scheme as an example:

1. Player 1: 8 colours, 0..7 3 bitplanes
2. Player 2: 8 colours, 8..15 4 bitplanes
3. Baddies : 48 colours, 16..63 6 bitplanes
4. Scenery: 192 colours, 64..255 16 bitplanes

Now, if the players never overlap on the scenery, it's okay, you
don't have to worry about the other bitplanes.

If you want players over the scenery, the make it only on, say 16 of the
scenery colours - saving bitplanes.

If you try to use ALL bitplanes ALL the time with EVERYTHING on the screen,
then a machine running at 32 MHz (TT) will be as slow as a 8 MHz (ST)
machine for executing graphics operations.

Further discussion on this line should probably be in rec.games.programmer!

I hate to have to post this publicly, but I've been trying for *days*
to find some permutation of your e-mail address that would work, and I
keep coming up dry. You're the *only* person so far who has claimed to
have this same problem *and* been able to fix it themselves. What is
this software you used? Is it available in the public domain anywhere?
What exactly is the SPEED POT? I'm desperate for any more information
you can give me about this...PLEASE respond!

If its coming from the flyback sometimes its just something vibrating and
can be stopped by gluing whatever is vibrating with some high voltage
sealant material. May take a bit of work to locate the vibrating area though.

1258. Re: Using GDB

Newsgroup: comp.sys.atari.st.tech
Date: 1991-02-04 11:50:42 UTC
From: gjh@hplb.hpl.hp.com
Message-ID: <GJH.91Feb4115042@ghiggins.hpl.hp.com>
Source record: 49199
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

Ron DiNapoli writes about using GDB:

++ I get "Program terminated with code #ffffff95" (again, not sure of the
++ number).

++ Does anyone know how to create good symbol files and good executables???
++ I can't use the -mshort flag because I need to have 32-bit ints (if that
++ makes a difference).

I've seen both problems experienced by Ron DiNapoli. I've recently been trying to port Elk (a Scheme implementation) to the ST. It compiles up but bombs out with a bus error (2 bombs), so I tried using jrd's GDB to debug it.

First reports of GDB indicated that it wouldn't work with GCC 1.37.1, later reports suggested otherwise.

My own experience suggests that GDB works fine on the set of test data supplied with jrd's GDB port. However, I've not managed to get it to work properly on the compiled Elk code.

I am currently oscillating between gulam and ksh-under-mint. (The Elk code tests the executability of argv[0], for some reason it can't find anything there under gulam but can with ksh, anyway ...)

GDB crashes out under KSH when reading symbols from the sym file. Scratch one route. Under gulam, it reads the exec and the sym file OK, arrives at the start after "run", reports "info functions", etc fine, but either 2-bombs out on "cont", or reports "Program terminated with code #ffffff95". Once, I got it to "cont" but it wasn't behaving *anything* like the way it does with the (precompiled) test code set. I chased down Edgar Roeder's uni-sb version of GCC, which has been reported as supporting GDB. Didn't seem to make much difference.

CFLAGS were:

-gg -O -DGEM -D__NO_INLINE__ -mshort -fcombine-regs -fstrength-reduce
-fomit-frame-pointer

are any of the above flags inimical to GDB?

the .ttp and .sym files were produced ..

```
gcc-ld -o scheme.ttp c:\gnu\lib\gcrt0.o $(O) -lpml16 -lgnu16
sym-ld -r -o scheme.sym c:\gnu\lib\gcrt0.o $(O) -lpml16 -lgnu16
```

I am using crt0.o and gcrt0.o assembled from the .s files distributed with Eric Smith's Mint libraries. The Mint libraries are not linked in to the Elk code.

Grateful for any suggestions.

BTW, when GCC compiling under gulam, "make" seems to 2-bomb out after some arbitrary period of happy mass compilation, ditto Ksh but less frequently. Under Ksh, problem seems to go away after the third/fourth round of mass compilation (with -g, without -g, with -gg, without -gg, ad nauseam) but return after a warm boot. Anyone shed any light on this --- I have a suspicion that it's a malloc() problem, but it's outside my field.

Cheers,

Graham

I have been trying to read both joystick ports from 'C' and have been using routines Ikbdws() and Bconin() without success. What I really want to do is read both joystick ports from within a GFA-Basic version 2 program and so I thought I would write a routine in Megamax C and then try to do the same thing in basic. Any code fragments in 'C' or even better in basic would be appreciated.

Did you try different environment styles under gulam? I have
set env_style mw
in my gulam.g; this makes most of my programs happy. Another useful
alternative (if your code expects environment strings like FOO=\0BAR\0
instead of FOO=BAR\0) is "set env_style bm".

Yes, -fomit-frame-pointer. gcc should have warned you that "-gg" and
"-fomit-frame-pointer" were incompatible.

I have had some success with gdb under the uni-sb gcc compiler and linker, but I have used

```
gcc -c -g test.c
gcc_ld -o test.tos test.o
sym_ld -r -o test.sym $GNULIB/crt0.o test.o -lgnu
```

(or something like that). I took a look at the gdb source, and it actually seems to support -g and not -gg (ie. dbx, not the native gdb format).

Aha! I suspect the 40-folder limit. You should be able to find a fix for it on your local BBS. If you already have foldrxxx.prg (or whatever it's called) installed, raise the number.

1269. How am I called? Why O Why...

Newsgroup: comp.sys.atari.st.tech
Date: 1991-02-05 13:43:07 UTC
From: jeroen@pluto.phil.ruu.nl
Message-ID: <1147@accucx.cc.ruu.nl>
Source record: 49209

Hi,

I have trouble with a routine posted on the net about a year ago.
The routine *should* distinguish between calls of a program from
the desktop, calls from another shell and from the auto folder.

Here's the routine (_BasPag is a global var pointing to the basepage
of the program):

```
#define FROM_AUTO 1
#define FROM_DESKTOP 2
#define FROM_SHELL 3

#include <tos.h>

int HowStarted(void)
{
BASPAG *p = _BasPag;
register int n = 0;

p = p->p_parent;
if((((long) (p->p_tbase)) & 0x800000L) == 0L)
return(FROM_SHELL);
while((p = p->p_parent) != 0L)
++n;
return((n == 1) ? FROM_AUTO : ((n == 2) ? FROM_DESKTOP : FROM_SHELL));
}

void main(void)
{
switch(HowStarted())
{
case FROM_AUTO: Cconws("Auto!");
break;
case FROM_DESKTOP: Cconws("Desktop!");
break;
case FROM_SHELL: Cconws("Shell!");
}
}
```

The problem is: from the auto folder it writes "Auto!", from a shell
it writes "Shell!" and from the desktop it writes... "Shell!".

Does anyone spot the bug in the source? Please mail me.

Thanx in advance, J.

1270. 68000 Assembler/Development System for 1040ST

1271. Cookie Jar information...

Newsgroup: comp.sys.atari.st.tech
Date: 1991-02-05 17:49:48 UTC
From: nut@nuthaus.UUCP
Message-ID: <8571204@nuthaus.UUCP>
Source record: 49211

I am currently writing a program which, if the system's cookie jar does not already exist (or is too small) will need to create a new one. I am somewhat familiar with the jar's specifications, but there are some things that I need help with.
First of all, do I have to install a reset-routine which clears the $5a0 variable? It makes sense to do so, since the globals aren't cleared after reset, but if I don't have to write the routine, so much the better (I like Pascal more than 68K!)
Second, is it kosher for my program to remove the cookie jar (or restore it to its old value) once it exits? Do GEM or TOS place cookies in there after system startup?
Third, what are the default system cookies? I have heard mention of them describing the system config, and if I am going through the trouble of installing a jar, I might as well put them in also?

As you can tell, I'm poor enough to not be able to afford the Developer's documentation. Hey, Atari, do you want to apply student discounts to the doc's? Most hackers are in college, and probably would provide a nifty new software base if given the doc's!

-- Adam

P.S. - Does anybody have example code for the aforementioned system-reset routine?

Hi,

I bought an Atari 1040ST over 2 years ago with the intention of
becoming a MIDI developer. I'm a full-time Software Engineer, and a
part-time Atari user. I've been trying to develop a software system
that would record MIDI data *PERFECTLY*.

I started out by using a polling loop querying the OS to see if
any MIDI bytes were in the (default) 128 byte buffer. This worked
somewhat usefully, but aside from the bad nature of polling, I found
that I would lose about 1 byte per 10,000.

I hit the books, bought Mark Williams C, and wrote an interrupt
routine that duplicates that the standard MIDI input code, but I write the
bytes to MY buffer, and time-stamp each byte when it comes in.

This method allows application freedom, as MIDI input will happen in
the background. BUT I STILL LOSE DATA WHEN I MOVE THE MOUSE, AND VERY
INFREQUENTLY WHEN I DON'T.

Does anyone know how to get around this? Someone must, since there
seems to be a lot of sequencing packages available for the ST. I've noticed
that some of them mess up, but some seem to be VERY stable.

I use a Roland TR505 for testing, with the tempo cranked up to the
maximum, and a pattern that contains as many drum sounds that I can fit
in on 16th note intervals...

Hello World,
Can anyone send me some startup code for Sozobon C that does not do anything *illegal* with its basepage... like the original version does. One that would work OK with RTX and/or MiNT (0.7) and debuggers (Specifically MonST2.0).

Thanks,
Andrew

Well what do you know, finally someone asks a question up my alley!
John, I wrote some networking software for the midi port and ran into
the same problem, the Bcon calls are too slow to retrieve information fast
enough(In TOS 1.0 they are anyway, TOS 1.4/1.6 its a little better) from the
input buffer. Solution? In increase your buffer size to about 4K, for really
TAXING operations, increase to 16K. I use an 8K buffer and don't have any
problems at all. Real time sequencing might be a different problem though.

An example in Mark Williams C that shows you how to do this is
in there, but it is used with the aux: port instead of the midi: port.

Message-ID: <11327@jpl-devvax.JPL.NASA.GOV>
Source record: 49215
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

I just got an OS upgrade to 1.4. I used to have 1.0.
The problem is that I can't get my machine to boot from
my harddisk. Several of the things that have occurred
and which I have tried are: (I have a homebrewed harddisk.
It has an ICD host card and I have the latest ICD distribution
disk.)
1) I have tried booting normally and get two bombs.
2) I have booted while holding the alt key down (This
is suppose to override the booting from harddisk)
3) I have booted with the harddisk disconnected then
reconnected it and could not access it.

I think if I can get to my harddisk I could eliminate all the
auto loading programs and then things would be fine.

Also if there are known accessories which do not work under 1.4,
or are programs which are no longer of assistance (ie. pinhed,
fatspeed, ...)

Thanks in advance for any assistance

You really must write your midi interrupt handler in assembler. Fortunately
this handler is pretty simple. The standard Atari interrupt handler is
actually pretty good, but you can optimize it slightly. For an example
of the source to the standard handler, see the Abacus Internals book.
The default buffer is much too small (128 bytes, I think). With a good
handler, a decent size buffer, and a good cable (most are crappy), you
shouldn't lose any data.

> This method allows application freedom, as MIDI input will happen in
>the background. BUT I STILL LOSE DATA WHEN I MOVE THE MOUSE...

This is true and it sucks big time! The problem here is that the
keyboard/mouse ACIA and the midi ACIA interrupt at the same level to
the MFP 68901. Also, the mouse packet parsing code is just too slow.
If you blast the midi port at full speed and move the mouse, its possible
that 2 midi characters will come in while you're parsing a mouse packet,
and BOOM! you lost the first one, since the hardware only buffers one
character. The midi handler cannot preempt the (slow) mouse handler,
and this is a hardware architecture problem.

The solution of course is to rewrite the mouse/keyboard handler, which is
pretty difficult, especially if you want to maintain compatibility with
the way the OS expects to find things. If you're writing a standalone
sequencer, this really isn't a problem, but for joe average it's difficult.

If you roll your own sequencer without the mouse handler, just _don't_move_
the_mouse_ (!) during critical times! (1/2 8^))

I hope this helps... Every profession sequencer writer has had to deal
with this.

It's not OK. GEMDOS's behavior in the presence of unexpected flag combinations is undefined. For example, some places in the code could check for (attr & SUBDIR) but some check for (attr == SUBDIR). So you might find that you can use the thing as a folder, but you can also Fdelete it, or if you Fcreate a file with the same name it'll get clobbered! This would be disaster for the files contained in the folder.

You're playing with fire.

our code is executed.

If the assembly routine saves ALL registers, it can push the MIDI byte
onto the stack and jsr directly to a C routine. If you allocate a
lot of local variables or nest function calls too deeply, you might
want to point the stack at some space allocated in your assembly
routine.

I would not be too surprised that you could generate enough
interrupts of higher priority that a MIDI interrupt might be
serviced after the next byte arrives. I haven't experienced this
problem but I haven't really TRIED to produce it either.

Be careful about using registers you haven't saved in your assembly
routine. At the time the interrupt occurs, you have NO idea what
might be in the registers. I kept having the temptation to believe
that I had access to the scratch registers of the C compiler.

For one thing you must set it for DS0, did you have a board with a
large ic, on it, if so this has to be by passed, it does not give a
side select line, also what is the Step Speed of this drive, some early
PC drives are 6ms, this can be a Big problem for the ST's, but you can
set the step rate with a program, but no good for running games..

Source record: 49220

I installed AT-Speed this weekend, and so far, it's doing great. My only quarrel with it at this point is that I can't get it to run Procomm. Other PC programs work great, and my ST communications programs run just like they always have. Is there some simple change within Procomm that I need to make? Or is there a switch in the AT-Speed installation software that I need to set? If anyone knows the answer to this problem, I'd appreciate your wisdom! Thanks,

Dave Jensen

>it's called) installed, raise the number.

Having experienced similar problems as described above using TeX ;-(
i came to the conclusion that it was memory management, not the 40-folder
limit (foldr200.prg didn't help; shuffling memory did sometimes. also
the available memory sometimes came down to a whopping 10k -- not enough
for TeX (I am stymied)).

My solution to this "feature": use tos 1.4. I am now running without
foldrxxx.prg && cache020.prg and have not experienced the problem.

>I would love to hide folders and protect their contents this way.

If it ever gets implemented in TOS, remember that sometimes one would like to
be able to delete a hidden folder, so atleast offer the possibility to unhide
hidden items on the desktop. Perhaps an option like 'show hidden' and make them
ligther on screen or something like that.
It also makes it easier to keep track on what is on the disk if the number of
bytes that is hidden on a disk is mentionen in the 'disk info' dialog as it
is in Neodesk.

I seem to have a problem installing PC-Ditto on my Megafile30+Mega2ST system. I have done it earlier at a 20 MB HD and it worked OK, but I just cant get it to accept that the dos file exists on the megafile30. When I start PC-ditto (whith PCDOS 3.2 on the HD) it just locks up! (By the way, YES I have read the manual (see above)). I have also used the program on the PC-Ditto disk to fix the boot block parameters (I know that they dont say that you should use it on a mega30, but if I dont, I just get "divide overflow"). My DOS bootdisk contains exactly the same PRG:s and works perfectly, finding my C,D,E,F partions with no problems. When I transfer them to my newly formatted HD (First formatted from GEM, then from PC-ditto with"format C:/S"), nothing works (No, i doesnt transter the Command.com from the boot disk either!)

Hello,

FIRST, I want to thank everyone who is reading and replying to
my posting...

I'm relatively new to the USENET, and tried to post something
yesterday, but actually sent a mail message by mistake...

ANYWAY, I wrote my MIDI input handler in the assembler provided
with Mark Williams C. I duplicated the code from the disassebled BIOS
listings in the Abacus Internals book, adding a timestamp, and depositing
the byte in by 32K length buffer.

I will attempt to write an entire level 6 interrupt handler, if
the is the only way out. From what I now understand, there's no way
around it.

I want to support the mouse AND MIDI, with MIDI being the number
one priority. I don't mind losing mouse events if I have to (while MIDI
bytes are coming in).

John

I am a new ATARI user who is full of questions. Hopefully some
of you can help me get started. There aren't any other ATARI users
in my area (that I know of) and the "good deal" I got didn't include
much documentation! Thanks in advance for any replies.

I need a description of the operating system. I would really like
to know how the desktop works, how files are managed, how
does the OS know what devices are connected, ect. Where can
I find one?

I have an ATARI 520ST with 500K ram (s/n# A11003969 - does that mean
anything to anyone???). What are my options for upgrading?

I have a printer that will not operate with the CENTRONICS cable (the
same printer/cable operate fine when attached to "one of those
other PC's"). How does the ST know if there is a serial or
a parallel printer attached? What is the correct cable
configuration to use?

What are my options for a hard drive? What type of HD am I looking
for? I now have two floppies - SS354's.

Is there a translation capability to read/write IBM & MAC 3" discs?

Are either of the monitors compatable with other PC's? I have a SM124
and a SC1224 as well. (e.g. I don't need two monitors,
simultaneously - could the one I'm not using be hooked as a
display for something else?)

Must I dismantle the unit to read the PROM version? Is there a way to
ask it? ...and what is the current version of the OS? If I don't
have the current version, how can I get it?

Thanks again for any help offered. I'm excited about the ST and
looking forward to becoming "more functional"!!

I am somewhat new to the Atari - we are moving our development system from a 1040ST to a top-of-the-line TT and having problems.

1) We use kermit to transfer files between all ~5 OS's in-house. However, the Atari kermit program refuses to receive any file with 8-bit characters in it. Text files in Image mode work; but 8-bit characters cause failure in any mode.

2) We use Mark Williams C for our product, yet the debugger "db" doesn't work on the TOS version on the TT. Mark Williams Co. said that Atari hasn't provided them with some necesssary files, and they don't have the programmers to update their product anyway.

Where can I get a new kermit? (The one we have is from 1985)
What is a real compiler that works on the TT? (We need real support)

no, I don't have ftp access. thanx in advance for help.

Interesting. A few months ago I bought a used copy of the prospero
fortran compiler, and there's a program PRL that you're supposed to
run before running any of the other stuff. I think PRL is ram resident
library stuff. Anybody know what Spice.lzh was written in?

Bud

Can somebody with some documentation give me information on the
Flopfmt and Protobt XBIOS calls?

On an unrelated note, is there any legitimate way to increase the size
of the RS-232 buffer?

Thanks,
entropy

get uniterm v2.0a or later. it uses 1k packets for its built-in kermit
(actually u can set it between 0 and 1000+ bytes (94 was original kermit
protocol. in addition, u get a very nice terminal emulator (vt100, et al)
and a tektronix 4010 (?) emulator plus dialer plus xmodem plus...

you should be able to find it at atari.archive.umich.edu. uniterm is a
very solid piece of work (i use it every day).

the unix version of c-kermit is available from columbia univ (i don't
remember the address). there may be a port to the st, but i never even
bothered to find it since uniterm is so nice (and free). c-kermit started
using extended packets somewhere around version 4E(067) or so (???). at
any rate, the latest release from columbia will have extended packets.

>no, I don't have ftp access. thanx in advance for help.

you can get uniterm by mail from the archive. read the FAQ for the archive
which is posted about once a month here. atari.archive.umich.edu is often
refered to as "terminator", its old name (terminator.cc.umich.edu).

Thanks for explaining that Allan. I confess I hadn't thought of that after
I was able to use the folder as normal. Are there any checks in TOS that
might cause such problems? If not, will it remain so? Seems like a good
idea to me. System files could go in a system folder etc.

>You're playing with fire.

You're right of course. I don't do it very often and I promise that if I
get burnt because of it I won't go badmouthing you or Atari. I'll just
learn my lesson. OK?

1298. Re: tos bug Was: Using GDB

Newsgroup: comp.sys.atari.st.tech
Date: 1991-02-08 10:55:28 UTC
From: gjh@hplb.hpl.hp.com
Message-ID: <GJH.91Feb8105528@ghiggins.hpl.hp.com>
Source record: 49151
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

I had a look at my system setup following Dave's suggestion. I find that the ICD HD driver already gives me 250 folders, so it can't be that. I too suspect memory management (malloc? sbrk?). It's a bit of a pain as, under Ksh, the commandline args output whilst compiling are single, unbroken lines, so I can't tell which file it was compiling when it bombed (the filename is about 3" to the left of my screen :-( )--- but it still leaves behind an improperly-compiled (improperly written/saved?) .o file, which needs to be deleted before restarting the compilation.

The only things in the AUTO folder are COPYFIX, FSELECT, ICDTIME and MINT. There's a 60k DOS buffer, a 20K disk cache and 250 folders (from the ICD HD driver). I wonder if I need to turn on the write verification?

BTW, Eric Smith noted that -fomit-frame-pointer si inimical to -g/-gg and that he expected GCC to have mentioned this fact (RTFM, Graham -- probably). Dave Megginson says that he's had success with GDB using the unisb GCC, but that the internal gdb stuff has been stripped out and it only produces dbx info. I rmember Edgar Roeder mentioning this --- but what's the net effect? I mean what effect does that have on the functionality of GDB?

Just to satisfy my curiosity ...

Has anyone else suffered from Error 66 (invalid program load format) errors on posted stuff? The recent nroff posting (manpager) yields this error, whilst lessbin was fine. I also remember jbammi once being surprised that a preloaded TeX binary he distributed showed the same error. What I find odd is that no-one else has mentioned any problems with the manpager. Is it just my system, I wonder?

I also had to recompile flib.ttp in showdvi-1.0. Now I've seen a README endorsing showdvi-1.0 from jbammi and would have thought that he'd have mentioned any problems. Flib crashed with an "fseek" error and GCC complained about the usage of a short. I (arbitrarily) replaced the short with an int and it seems to work OK --- at least it will create libraries and showdvi can use them OK. I believe that the fseek problem might be down to the fact that the binaries were compiled with Turbo-C, but I'm curious to know whether anyone else has had the same problem.

BTW, dviatari crashes out on Jeff Long's deskjet font files (300 -> fonts), apparently seeing Character 0 more than once. Anyone got this to work successfully? I tried using single fonts but all dviatari would print was (and here I quote) "G000680c6" at the top of each page. However another dvi printer driver (dvidsk5) worked fine on those same fonts. I suspect a problem with dviatari's compilation --- anyone seen the sources of this?

Thanks for the info. Still trying.

Cheers,

Graham

There is a file PRL.TOS, stick it in your auto folder. Its purpose is to
supply all the library routines that the program requires.

I think you have to like 68k! I wrote such a programme on my own, in
assembler language. You are right $5a0 is not cleared after reset. So you
have to do this, because of uninstalling the cookie jar the pointer
of $5a0 points to a so called cookie jar... your system may be confused of
this!

> Second, is it kosher for my program to remove the cookie jar (or
>restore it to its old value) once it exits? Do GEM or TOS place
>cookies in there after system startup?

I think its better to remove it.
TOS places several systemcookies. For example one for the processor used.
I can send you a list of the systemcookies later on. Please read on
'News' again, 4 or 5 days later, and watch out for my second reply.

Yes, you have to run PRL.TOS before you run spice.ttp. PRL.TOS is included
in the .LZH file. Unfortunately spice.ttp/prl.tos bombs out if ataris
cachennn is resident.

How about a constructive discussion on programming environments and tools
that people use on their ST's? Many would benefit I'm sure (including me
:-).

My big dilemma is trying to find a 'good' make and cc wrapper for
compiler 'x' (where 'x' might be MWC, Turbo-C, Alcyon (shudder), etc).
Any ideas? Ideally, I'd like them to work in harmony under Gulam.
I've looked at atari.archive and am hoping for more info. Pointers to
Commercial applications would be useful as well.

Some question for Emacs 3.10s hackers:

(1) How to I turn off that bloody function key menu (alter something
in the emacs startup file I suspect).

(2) If I'm running it from a command line, how do I tell it where the
home directory is (for emacs startup, etc).

I'm sure this is in the doc somewhere but I haven't stumbled over it yet.

Thanx.

Joe

1312. Weird Keyboard Behavior with Gulam when Typing Quickly [also Elvis]

Newsgroup: comp.sys.atari.st.tech
Date: 1991-02-08 18:44:43 UTC
From: dmb@cscwam.umd.edu
Message-ID: <1991Feb8.184443.26162@wam.umd.edu>
Source record: 49148

I've been using Gulam for quite some time and started using Elvis a few months ago. The problem is that when I type certain pairs of capital letters very quickly Gulam seems to convert them to function key scan codes. E.g., I type "MI" quickly and Elvis gives me "M#<s>f3I". This happens quite frequently, probably because I never actually learned to touch-type, but rather acquired a sort of "burst-mode" method, the eventual evolution of several-finger hunt-and-peck. (What you get for learning to program at age 9, I guess.)

Anyway, I traced the problem to Gulam. Try typing "MI" on the command line, and Gulam will say "Mark set" or something like that, as though you typed F3. (I suppose it could be something in the AUTO folder as well, but since I know Gulam replaces the keyboard handler I am assuming it's its fault.)

Does anyone know how I can fix this? Is there some way to turn off Elvis' expansion of Shift-F3 into #<s>f3? It's driving me crazy! And I really don't want to go back to LeVee (32K file limit), or STevie, since I otherwise like Elvis a lot. At the least, can I get source to Elvis and compile out the function key support?

Thanks all,

Dave Baggett

In article <91032.112332REEVES@SLACVM.SLAC.STANFORD.EDU>, Terry Reeves writes:
|> The Uniterm manual suggests that you should try cntrl-M.

Whoa!! The question was "how to get Uniterm 2.0e to send a carriage return".
The example requested was to get the character string "vax*" sent from f1.

Looking at the macro language section, the syntax is as follows:

```
send('vax*\r') # if you want the CR
send('vax*\n') # if you want the NEWLINE
```

To get it into a function key macro, the macro is %send('vax*\r'),
meaning that you must escape macro-language function calls with '%'.

Note that the string handling stuff also supports "\0xx" for an arbitrary
octal string. Since 7-bit ascii won't fit into 2 octal digits, I believe it
might be HEX and not octal - but I haven't tried anything more than '\r' and
'\n', both fo which work just fine.

IMHO your best bet is buy MINIX. It looks like V7-UNIX,
comes with a reasonably full set of UNIX utilities
(including cc, make,elvis - a vi look-a-like, elle - an
emacs look-a-like, and a real shell.) And, except for the c
compiler and elle you get =source code= for everything! MINIX is
available from Prentice-Hall (or any bookstore that deals with
them) and has a list price of $169. The minimum configuration
you will need to run all of the utilities is a 1 meg machine and
you should have 2.5 meg (or better) with two double sided floppy
drives.

I thought Dave Beckemeyer would answer this 8-). Get his Hard Disk Sentry program it should work on larger partitions (I hope so, I keep meaning to buy it). Dave said it would do that himself here on the net some while back. I could dig up my copy of the posting if necessary.

1317. Re: Weird Keyboard Behavior with Gulam when Typing Quickly [also Elvis]

Newsgroup: comp.sys.atari.st.tech
Date: 1991-02-08 23:24:09 UTC
From: carter@cat27.cs.wisc.edu
Message-ID: <1991Feb8.232409.11607@daffy.cs.wisc.edu>
Source record: 49157

dmb@cscwam.umd.edu (David M. Baggett)
Writes:

I've been using Gulam for quite some time and started using Elvis a few months ago. The problem is that when I type certain pairs of capital letters very quickly Gulam seems to convert them to function key scan codes. E.g., I type "MI" quickly and Elvis gives me "M#<s>f3I". This happens quite frequently, probably because I never actually learned to touch-type, but rather acquired a sort of "burst-mode" method, the eventual evolution of several-finger hunt-and-peck. (What you get for learning to program at age 9, I guess.)

Anyway, I traced the problem to Gulam. Try typing "MI" on the command line, and Gulam will say "Mark set" or something like that, as though you typed F3. (I suppose it could be something in the AUTO folder as well, but since I know Gulam replaces the keyboard handler I am assuming it's its fault.)
Does anyone know how I can fix this? Is there some way to turn off Elvis' expansion of Shift-F3 into #<s>f3? It's driving me crazy! And I really don't want to go back to LeVee (32K file limit), or STevie, since I otherwise like Elvis a lot. At the least, can I get source to Elvis and compile out the function key support?

Is there a way to fix this problem? I'll give you a hint, it ain't Gulam's fault....

But I am sure if you look at the keyboard controller circuitry someday when your feeling board you'll kinda say: "Hey wait a second here, THATS NUTSO.".

OK, so I knocked my machine, who cares, its not a BUG its a FEATURE OK?

In article 4fb2916e.20b6d, Walt Weber points out how I may have given incorrect advice for programming Uniterm to send the string "vax*" followed by a carriage return when the F1 key was pressed. He then presents an example of how to use macros within function key definitions to achieve the desired effect. However, my solution does work and is simplier if all you want to do is send the string "vax*" followed by a carriage return. There is no need to imbed the string in a macro. Now if you need some real smarts in the characters sent, then a macro is essential.

From: bgrave@ub.d.umn.edu
Message-ID: <876@ub.d.umn.edu>
Source record: 49161

I've got a couple of questions about Hard-drives and the Mega 2 ST. The DMA port on the back of my Mega is a 19 pin parallel type connector. I've no idea how hard-disks work having no experience with them, but I have heard that most standard SCSI controllers have a 40 or 44 pin connector. Is this true?

If so, is there some special type of controller I would have to invest in to get a HD to work on my machine?

Who makes the MegaFile drives and are they reliable (like Quantum drives)?

Etc and any other info you think I might need to know...

Thanks for any and all help.

>rmember Edgar Roeder mentioning this --- but what's the net effect? I mean what
>effect does that have on the functionality of GDB?
>

I've had success with gdb, but it's been very mixed. When I try it on large programs, there is not enough stack space for the symbol table (yes, it uses alloca, I guess), and on medium-sized programs, it often loses synch with the source code. Oh well, ... for now, I just bring my source to a Sparcstation, recompile it there, then use gdb to find the error--it's faster than wasting my time on the ST trying to do it.

It would be __great__ if someone could port szadb to gcc, so that it could read the gcc symbol tables. Since gcc can leave local as well as global symbols in, it would be pretty useful.

>Jim Bernatowicz (jbernat@andy.bgsu.edu)

I have two ST296Ns, they are fedd by a 65W power-supply.
Remember to shield the power-supply with metal and use thick enough
cables. Fan won't be bad either. I think you'll need something over
150W. Four drives at startup draw quite a large amount of amperes out
of the power. If you put some kind of a delay to power them up one at a
time, smaller power would be enough. 150W powers are quite expensive!
(150W +-12V, +-5V)

I like using Gulam. It has a command line interpreter, one can write command shells (.g files), it has a ue that I don't use, and a terminal emulator. Now, I prefer calling an editor such as STevie (a near vi clone). Gulam is available from atari.archive.

>I also sorely need a ramdisk facility of some sort - I've talked to
>atarioids who say they have them, so I assume it's not difficult.
>With 6 meg to kill, and a DOS that Really Thrashes the hard disk,
>I *need* a ramdisk.

There are tons of these around; I think every beginninng programmer has written one. However, the best is one I have found is one that happens to have evolved out of the work of several programmers and gone through several public versions: EDISK. I think that version 2.1 is the latest. It comes with a program ECONF that "configures" the EDISK program. It is the first (and maybe still the only) program to set the volume id for the ramdisk. Amusing. I have not figured out a use for it though. Again this program is available from atari.archive.umich.edu.

Atari.archive.umich.edu is arguably the best archive site around, certainly the best in North America. It is both an ftp server and a mail server. The folks there are serious about keeping it current.

Hi Andreas and David,
I have also had the same problem on Megafile 30's; but not on
my SH205 (Megafile 20 before Atari change the name), the SH205 is modified
though. I replaced the 20m mechanism in the SH205 with a 40m mechanism (which
Atari's HDX does not support), so I am using Supra's HD Utilities. Also on my
Mega I installed an internal HD with ICD's AdSCSI Micro Adapter, I installed
PC-DOS on it also with no problems.
I believe I heard a rumor that Atari HDX is incompatible with PC-DOS
for some bizarre reason. You may want to try a 3rd party HD driver .SYS on
your Megafile 30, you should backup your C:\ partition first though. Bye....

From: cliff@jarthur.Claremont.EDU
Message-ID: <10745@jarthur.Claremont.EDU>
Source record: 49166

I'm having trouble getting g++ to work on my Mega ST 2.

The problem is that it doesn't like to use the normal gcc libraries such as stdio.h strings.h. It gives me parsing errors on the functions fread() and fwrite() in stdio.h. (lines 145 and 146)

Does anyone know how to fix this? G++ should be able to handle normal C program with no/little modifications (I know, I've tried with G++ on my school's machines). What's wrong? My env variables are all set properly as far as I can tell.

I'm using G++ 1.35 and GCC 1.36.

HELP!!!!

--Cliff Stein

BTW: Are there any newer versions of these?

1328. Re: Hard-drive questions

Newsgroup: comp.sys.atari.st.tech
Date: 1991-02-10 08:34:01 UTC
From: scale@abode.wciu.edu
Message-ID: <1991Feb10.083401.1926@abode.wciu.edu>
Source record: 49167

So long as you have a Mega and want a hard drive, I would recommend buying an ICD AdSCSI Micro Adapter and a 3.5" SCSI hard drive. The Mega has an internal DMA port for the cable of the AdSCSI Micro to connect to, the AdSCSI Micro itself plugs into the hard drive, the hard drive is placed into the provided bracket that mounts to the existing hole in the Mega motherboard. The Mega motherboard also has an unused power connector for the hard drive to plug into.
I would also recommend using a Conner or Quantum hard drives. I am using a Conner CP3100 and am quite happy with it. Bye.....

Just use an IBM/PC power supply. Looking in PC WEEK, one sees 230W power supplies for ~$55 US. PC cases are also lots cheaper than special disk cases, and have places in them for power supply, several disks, etc. You might even get a better deal if you buy case & power supply at once.

Flopfmt() formats an entire track on your disk. It may be used for 9 or
10 sector formats. 11 sectors are not accepted! In TOS 1.02 or higher you
may pass interleave and spiral factor -- TOS 1.00 seems not to evaluate
these parms.

> On an unrelated note, is there any legitimate way to increase the size
> of the RS-232 buffer?

Hmmm ... legitimate? :-)

You may get the control blocks with Iorec() and change the pointers to
the input and output buffers. Don't forget to restore them when terminating
your program!!! This method works and I'd think it's legal, since you use
documented structures and sys calls.

> Adam David. adamd@rhi.hi.is

Well is this the info you wan't, Paddles are at $FF9210-$FF9216 they
are all long words but only the right word is read in this order
x Pal 0, Y Pal 0, X Pal 1, Y Pal 1, also $FF9220-$FF9222 are long words
for the light pen, only the 10 right bits are read, X then Y , the resolusion
for X direction,at 320 is 4 Pix, 640 = 8 Pix and 640M = 16 Pix, a correction
has to be applied for 640 and 640M that is shift one bit left for 640 and
2 bits left for 640M. The Y direction is to one Pix, all modes.

Uhm, thanks...I suppose I wasn't specific enough. I know what the
function does, I don't know what parameters to give it. Perhaps
someone could post a piece of code to format drive A with 80 tracks
and 9 sectors and write the proper boot sector? I can handle it from
there.

>> On an unrelated note, is there any legitimate way to increase the size
>> of the RS-232 buffer?

OK, could you document the structures and sys calls for me? I'm
posting these questions because I don't have any documentation, not
because I'm too lazy to RTFM. Restoring the pointers is not an issue
because I'm using this in a TSR and I _want_ the new buffer to stay in
effect after termination.

Many thanks,

Cliff Stein writes:

++ I'm using G++ 1.35 and GCC 1.36.
++ BTW: Are there any newer versions of these?

GCC versions have reached 1.39 on terminator, but only 1.37.1 appears in binary form (1.38 and 1.39 are in "diff" form).

What I'm concerned about is that the GCC-using ST community is dependent on *someone else* doing the cross-compilation to get these diffs into binary format. (Or are they --- has anyone got a GCC v1.39 executable by compiling it up on an ST?)

For a brief period last year, we lost our primary supplier (Hi jbammi!), what happens if it's permanent next time? (He might swap his ST for a TT [or best offer] and then where are we?)

I have tried to follow a path designed to produce an ST GCC-bootstrap distribution (get the compiler to compile its own sources, and work through the libs, gdb, binutils, etc) but I find that it's *extremely* difficult to

a) collate everything required --- it's a dynamic list!
b) integrate the various gcc, gas & ld options.
c) track down the various library sources (e.g. termcap)

I tried to compile gcc v139 but bison fell over a .y file --- now I have to find out whether GCC 1.37 and byacc are still in synch. These problems generally don't appear when cross-compiling on Eunuchs boxes for example --- but they do tend to arrive in hordes when ST-bootstrapping.

Cheers,

Graham

>I did read some info that you MUST USE IBM DOS, Not MS DOS, this could
>be one of your Problems..
I use IBM Dos, and as i said, it works on my old SH205 20MB HD (unfortunatly
I have sold it to afford the megafile 30)

1338. REPOST: binary write question

Newsgroup: comp.sys.atari.st.tech
Date: 1991-02-11 13:27:57 UTC
From: ericco@ssl.berkeley.edu
Message-ID: <ERICCO.91Feb11082757@soc1.ssl.berkeley.edu>
Source record: 49178

On the slim chance that my first posting was not distributed, this is a repost. My question is basic: how do I write character code 10 using write, as in:

```
{
char c = 10;
int fd = open("test.dat", O_BINARY|O_WRONLY)
write(fd, &c, sizeof(c));
close (fd)
}
```

When I do this, i get carriage return AND linefeed in the file "test.dat". I'm using Laser C.

Thanks in advance,
Eric

>attempt one with some special features. Any language of source code is fine.

most ramdisk programs are small. you will probably have more luck in getting source by getting a disassembler and making source from an executable. note that you will get assembler, and that the disassembly may have problems if the original code had data in the text segment (common if original source was assembler). unfortunately, this is often the only way to get source for some otherwise PD programs. it is also a good way to learn, however...

there are a couple of halfway decent disassemblers out there. check the archives. i started to write an intelligent disassembler (i.e. one that could handle imbedded line A, data in text, etc) but finally gave up once i knew enough assembler to hand edit and fix the output of other disasms. since i do not do this too often, it was a good compromise.

1340. Local Atari User Group - ST meeting - Wed Feb 13/91

Newsgroup: comp.sys.atari.st.tech
Date: 1991-02-11 17:13:22 UTC
From: daroloso@watmath.waterloo.edu
Message-ID: <1991Feb11.171322.28480@watmath.waterloo.edu>
Source record: 49179
Cross-posted to: uw.sys.atari,comp.sys.atari.st,comp.sys.atari.st.tech

At this month's ST meeting of KWEST:

1) An introduction to APL (available from our library).

2) Demonstration of Powermonger (from the makers of Populous) and 2
Spy vs. Spy games: The Island Caper and Arctic Antics.

3) Further examples of what can be done with Antic's Cyber Studio.

4) If we can get someone to bring midi cables, we will demo the new
shareware Midimaze II from Germany (also available from the library).

5) TWO (2) disks of the month plus the February issue of "The Hard Copy"
full of reviews and articles.

6) If you have any questions, problems, or new software, bring them along.

The Kitchener-Waterloo Eight Sixteen Thirty-two (KWEST) Atari user group,
has a separate 8-bit meeting and 16-bit meeting.
We meet monthly, have special interest groups (SIGs), associated bulletin
boards, public domain libraries, and a newsletter "The Hard Copy".

I am on the executive of the group
so I should be able to handle most questions or
get replies from the rest of executive.

The group welcomes new members and visitors with
8-bits, 16-bits, or those just curious.

Meetings held at the University of Waterloo in the
Math & Computer Building.

Rooms open at 7:00 pm. Meetings start at 7:30 pm.

Call 579-3695 for details.

Next Meetings
****

16-bit (ST) - Wednesday, Feb 13, 1991
DCS Course Room, Room 2009 (2nd floor)

Hope to see you there,
Dani Roloson

Yes. HD Sentry will work with larger partions, even using the "logical block" scheme that HDX 3.x (and now 4.x for the TT) use.

It is a commercial program with a sugg. retail price of $49.95. It is in distribution and should be available at a loval store or mail-order house. It can also be ordered directly from Beckemeyer Development by calling (415) 530-9637 on Monday, Wednesday, or Friday betwen 10AM and 5PM Pacific time. You can also call the BBS at (415) 530-9682.

There are plenty of useable MAKE's around, you should be able to get one from any good PD Library. Good CC's are harder to find. I rewrote the Sozobon CC to work with Turbo-C, I can post it if there's enough interest.

Note ; CHKDSK3 is not for general release as its for Developers only,
but I would like to know more about Molasses, Have not heard about that
one, I do have 2 German ones but they don't do 32meg partitions, but
one of these lets you set your R/W options and some otheres, but can't
decypher the German, it gives you full report on the files that its working
on, the R/W option lets you set which files you wan't at the front,
(read) and which ones at the back (write), but there is another option
that I can't work out, I don't know if its PD, as there is no copyright
notice from what I can see..

The following is an excerpt from the Minnesota Atari ST user group newsletter, which goes in the mail tomorrow (assuming I get the laser printing done).

THE LAST WORD

By Steve Yelvington

Well, somebody's finally done what should have been done a long time ago: written a genuine alternative Macintosh-compatible operating system. Not just a Mac emulator. A complete Mac replacement.

It's described in the Jan. 28 issue of InfoWorld, a weekly personal computer trade magazine.

A company called Nutek Computers Inc. has cooked up replacements for Mac ROMs and the disk-based portion of the Mac software (system and multitasking Multifinder). It also has three custom chips that can form the heart of a Mac-compatible, and it's looking for companies to produce the hardware.

This is different from Dave Small's Spectre, Magic Sac, AMAX and other Mac emulators for the Atari ST and the Amiga. They require you to track down a genuine Mac ROM chip set and a copy of Apple's system software.

Apple has suddenly clamped down on Mac ROM chips, and Apple dealers can get them only by turning in the old chips they're replacing -- or by paying a whopping surcharge. Apple seems determined to keep Spectre et al from catching up with current top-of-the-line Macs.

Nutek's technology sidesteps the whole problem by providing its own alternative software, developed in a ``clean room'' environment based on Apple's specifications without seeing a line of Apple's code.

And although it runs Mac software, it avoids ``look and feel'' copyright infringement by not looking like a Mac.

How can that be?

Well, Nutek has licensed the Motif user interface from the Open Software Foundation. OSF is pushing Motif as a friendly look for new Unix systems. IBM has adopted Motif for OS/2. And Geoworks has adopted Motif for GEOS on smaller PC clones. It's an attractive and well thought-out windowing system.

When a Mac application opens a window, it gets a Motif window. When it puts up a menu bar, it gets a Motif menu bar, attached to a window instead of glued to the top of the screen. This is actually easier to understand than Mac Multifinder's method of changing the content of the menu bar as you switch among concurrent applications.

I haven't seen any of Nutek's software running, but the pictures sure look good.

Dave Small has said he's not interested in making a Spectre that can use 256K Mac II ROMs, the current state of the art. One reason may be that they're darned near impossible to get. (There is a report that Apple is considering licensing Mac ROMs to other companies for $500 to $1,000 a pop).

If Nutek makes its alternative system technology available at a modest price, the whole picture may change.

(The rest of the column goes on to discuss TT and Apple pricing, and is therefore omitted here.)

This note is only moderately relevant to these newsgroups so I'll make it brief.

I've accepted a job in Pasadena, California, and will be leaving the University of Michigan after February 28th. While I will still be on the network somewhere, I will probably not be very active maintaining files on the atari.archive site any more. With any luck my STs will survive the move, however, and I'll still be working on ST stuff in my new location. (And bigger and better things too, of course!) Have fun...

You can use file-I/O on another level: Atari GEMDOS calls.
It would look like this:

```
int f;
if (newfile)
f = Fcreate( "test.dat", 0 );
else f = Fopen( "test.dat", 2 /* for read/write */ );
Fwrite( f, (long)(sizeof(c)), &c );
Fclose(f);
```

1355. Some questions about how hard disks are connected to ST's

Newsgroup: comp.sys.atari.st.tech
Date: 1991-02-12 12:59:16 UTC
From: john@castle.ed.ac.uk
Message-ID: <8448@castle.ed.ac.uk>
Source record: 49047

I gather that if I want to connect a hard disk to an ST(E) I need a host adapter (DMA -> SCSI) (ICD etc) and a SCSI hard disk. If I want to use a ST506 disk then I need a SCSI to ST506 controller (Omti etc).

What I want to know is :-

1) Where is the software for the hard disk driver ? Is it in TOS (1.6?) or a separate driver supplied by ICD etc. If the latter - is it in PROM. If not how does "autoboot" work ?

2) Has anyone attached an ST506 drive without going the SCSI route ? ie. by building their own hardware (+ software?). (I guess the answer to this question depends on question (1)!!

Replies by email would be great since I suspect that these questions must have been asked before although I haven't noticed any in the last six months or so.

Thanks,
John Hannah

1356. form_do() Questions

Newsgroup: comp.sys.atari.st.tech
Date: 1991-02-12 13:57:52 UTC
From: alex@hpgnd.grenoble.hp.com
Message-ID: <17750006@hpgnd.grenoble.hp.com>
Source record: 49068

Hello,

1)

Does anybody know of sources of form_do() available somewhere ?
Or sources of an alternative form_do() ?

2)

I have experiment troubles with form_do(). It seems to do not redraw
the outline of radio buttons when they are stick together and when
the currently selected radio-button changes.

Is anybody aware of that? and what could be a work around ?

3)

What rule is used to give the focus to TEXTEDIT fields when the TAB
key is pressed ? Some times, I found that some TEXTEDIT fields are not
reachable unless the user directly points within it with the mouse.

According to Electronic Engineering Times (Jan. 28, 1991, p. 10)
"Startup claims legal Mac-clone chip set", the company, Nutek Computers,
claims to have developed a "Mac-like OS" in a software "clean room",
that is, where the developers had no access to Apple code. The question
yet to be answered is whether or not their approach will actually
withstand a legal challenge.

In order to avoid the "look and feel" issue, the OS uses a Motif interface
instead of the Mac desktop.

1359. catch SLM DMA-calls --- How?

Newsgroup: comp.sys.atari.st.tech
Date: 1991-02-12 16:17:09 UTC
From: nico@cs.ruu.nl
Message-ID: <4832@ruuinf.cs.ruu.nl>
Source record: 49046

I have a NEC SilentWriter LC-800 laserprinter.
It was cheap, but it doesn't understand postscript. All it can do is print plain ascii (diablo emulation) and print bitmaps, apart from some exotic features.
This is a shame, because I cannot use DTP programs now, or even print DVI-files (the ones that are produced by TeX).

I have thought of the following:
The Atari SLM laserprinter is also not very smart. As far as I'm informed, about all it can do is print bitmaps, which are built in memory. But there is a lot of software which can use this capabitlity!
If only I could cath the SLM output, stick some LC-800 control codes in front of it, and send it to the printerport. In other words: I'd like to make a SLM-to-LC800 emulator.
This would not be too hard if the SLM were accessed via the printer port, via the normal BIOS I/O routines. But here comes the problem: The SLM is accessed via the DMA port, for speed.

Is there a way to catch the DMA-calls to the SLM, and redirect them to my emulator, which drives the printerport? Of course, I still want my hard disk to function properly.
Is there anyone out there who can give a hint on how to do this?

Thanks for any information,

1360. How do I zoo?

Newsgroup: comp.sys.atari.st.tech
Date: 1991-02-12 16:24:22 UTC
From: pdel@ADS.COM
Message-ID: <##+&S|_@ads.com>
Source record: 49045

Howdy, I'm having a problem unarchiving files, hope someone can help.
I've been downloading .arc files from terminator with no problem, so
decided to move up to .zoo stuff to prove I'm a real man.

Well, I've yet to prove my manliness. I'm using the zoo archiver that
comes with starter.tos
Here's what I'm doing:

1. - double click on the zoo.ttp application
2. - Command line appears waiting for me to pass a command
3. - I type ' zoo -extract filename.zoo filename ', like it
says to in zoo.man
4. - It thinks for a few seconds and then takes me to a kind
of help screen showing the available commands, and also
that I should type ' zoo h ' to get help.
5. - When I type ' zoo h ' it goes back to item 4. above.

6. - What am I doing wrong? I've tried a few other things, including
putting the .zoo file in the same directory as the zoo.ttp program,
as well as specifying pathnames, ie., ' zoo -x d:\filename.zoo d:\file-
name, but still it takes me to item 4.

7. - If there are any men out there who can help, I would be most grateful
and will mention your names among people of high honor.

8. - Please no flame-mail about being sexist, if you are female I welcome
your help too.

1361. MFPINT question: How does one obtain the CURRENT interupt handler?

Newsgroup: comp.sys.atari.st.tech
Date: 1991-02-12 16:45:23 UTC
From: miskinis@aisg.enet.dec.com

Hi Guys and Gals!

WELL, I'm the guy who posted the problems I've had in performing
MIDI realtime input that;s 100.0000% accurate...

From the replies I've received, it has become apparent that the
entire level 6 interrupt handler must be re-written in order to accomplish
accurate realtime MIDI recording.

I've build a prototype shell that allows *MY* code to execute
when a level 6 interrupt is encountered. I'm using the XBIOS function
MFPINT to replace the standard interrupt handler.

BUT(!) How can I find out what the original vector is? It
seems that MFPINT returns NOTHING!

Boy I'm glad I didn't quit DIGITAL to persue full-time MIDI
software development for the Atari platform...

Don't be fooled by claims that XBIOS and BIOS handles MIDI for
you. It does, but not under heavy (professional) scenarios.

John

P.S. I've been leary of becoming a registered Atari developer, since
I've invested ~$10,000 in equipment to persue music software
development. Paying a fee to the computer manufacturer in order
circumvent a problem (IN MY OPINION) that is inherent in the system
software, supposedly on "this computer is made for music" to
me seems quite unrealistic.

Perhaps with the rumoured Mac OS clone coming soon at a dealer near you, Spectre will be saved. It seems to me that an intelligent company selling a cloned edition of the Mac ROMs would not halt their distribution to a paying customer (maybe GBS could even make the entire thing into a card and not bother with the cart!).

1364. 1.44M external floppy on ST?

Newsgroup: comp.sys.atari.st.tech
Date: 1991-02-12 22:25:26 UTC
From: <>
Message-ID: <3575@ncrwat.Waterloo.NCR.COM>
Source record: 49087
Cross-posted to: comp.sys.atari.st.tech,comp.sys.atari.st

I think my last post must have landed in the bit-bucket... Oh
well... If all else fails, try again...

I've got an Atari ST (one of the old Nov.20/85 1040's) and just
bought a 1.44M floppy drive to attach as drive B:...

QUESTION ONE
Do you need to do anything special to get 1.44M out of it? I can't
seem to get it to read a HD disk... I've found a SW/PD formatter
called Diamond Format, which formats to 1.44M (or 1.6M if you use
more sectors than usual). It also seems to be a stand-alone portion
of a hard drive backup program. Do I need to find a special driver
or something? The drive works fine as a double density...

QUESTION TWO
Does anyone know where I could find a 14 pin DIN (ie, the ST's external
floppy drive port) plug adapter, that has a female 34-pin (ie, the
floppy drive's bus) port on the other end? Or am I doomed to building
one? Given the half-dozen or so 3rd party manufacturers of external
drives for the ST, a part like this HAS to exist, right?

Chris Herborth,
[Guest-posting with Brian Gamble, esq.]

Note from Brian Gamble:

Neither one of us knows much about these Atari news groups. Post replies as
you see fit, or EMail to me at the address below. I will see that Chris
gets any EMail promptly.

Thanks for your help

1365. Daisy-chaining ACSI drives

Newsgroup: comp.sys.atari.st.tech
Date: 1991-02-12 22:48:05 UTC
From: ncalvin@oracle.uucp
Message-ID: <1991Feb12.224805.109@oracle.com>
Source record: 49051

(apologies if this topic has already been mentioned too many times)

I'm running into difficulties connecting a Megafile 60 (type SEA5065)
and a Syquest removable drive to my 1040STE. I have the Megafile set to SCSI
#0, and the Syquest, plugged into the Megafile, set to #1, yet I'm unable to
read data from the Syquest. Both drives work fine if connected to the STE by
themselves. I tried flipping the DIP switch marked "X" in the Megafile, which
then allowed me to access the first 130 sectors in each partition on the
Syquest, but the rest of the disk is still unreadable. I have the feeling
there is something else I need to do to the MegaFile, but my manuals are
absolutely no help on the problem.

Internals: Megafile 60 appears to use an Adaptek 4070 board with a
Seagate ST277N-1 drive; the Syquest drive and controller plug into a
later-model Supra ACSI/SCSI board. I've been attempting to use Supra Utilities
v3.00 with both drives. I have access to Atari HDX 3.02, but was under the
impression the Atari hard disk utilities couldn't deal with multiple drives -
and, furthermore, Supra recognizes the Syquest at SCSI #1 while Atari doesn't.

TOS does have a small routine to read the boot sector and execute it
if its set for execution. all bytes in the boot sector must add up to $1234
this can then load the hard disk driver, or any other driver for that matter.

Note; the Hard Disk driver can be loaded from Cartridge, or Floppy
The order is Cartridge, Floppy A. B ??, then Hard Disk, (Devices 0-7)

> 2) Has anyone attached an ST506 drive without going the SCSI route ? ie.
> by building their own hardware (+ software?). (I guess the answer to
> this question depends on question (1)!!

Yes the Germans have done that, (don't they allways) using a PC hard disk
controller and a home made host adapter, plus patches to the TOS roms, or
a program in the Cartridge port.

If you've got the memory (2 megabytes or more) the various gnu utilities
that have been ported to the ST provide a very nice, Unix-like
environment. I use gcc, gnu make, and gulam most of the time, with
bash for running Unix shell scripts or for when I'm running MGR; the
latter two require MiNT, although there is a TOS version of bash as
well. Add a few other utilities (like diff, patch, wc, and some form
of emacs) and you have just about everything a programmer could want.
All that's missing is RCS, and Allan Pratt mentioned that he's working
on porting this.

1369. STe Programming info (long)

Newsgroup: comp.sys.atari.st.tech
Date: 1991-02-13 10:52:16 UTC
From: D.C.Halliday@newcastle.ac.uk
Message-ID: <1991Feb13.105216.18587@newcastle.ac.uk>
Source record: 49060

I notice that alot of people have been clammering for information on the STe recently. Some time ago a Mathew Lodge of ST world (UK mag) wrote the following. This information has appeared here before in 3 parts and has been published by various people in various magazines.

It should be noted that you should not hold this information to be gosble and if you wan't to be sure of correct information get the Developers kit. So if there are any errors don't blame Atari or Mathew lodge but yourself.

Now there is no excuse for not writing STe specific SW so how about some nice Demos.

Dave Halliday
(D.C.Halliday@newcastle.ac.uk)

00 -12 dB
01 Mix GI sound output (ST sound chip)
10 Do not mix GI sound output
11 Reserved

Sampled sound data is stored in memory as a series of bytes, which represent a speaker displacement from -128 to +127. Zero represents the neutral or middle speaker position. Playback is programmable at one of four rates : 50kHz, 25kHz, 12.5kHz or 6.25kHz.

During the horizontal blanking phase, samples are fetched from memory by the DMA sound chip, and fed into a Digital to Analogue Converter (DAC).

The output of the DAC is then filtered by a four-pole low pass filter to a frequency equal to around 40% of the sample frequency. The signal then passes through a two pole 16kHz low-pass filter, and fed into the National Semiconductor Volume/Tone controller (LMC1992). The final output is available from the RCA jacks on the back of the STE, which can be fed into an amplifier and hence to speakers, headphones etc.

Both stereo and mono sample replay is provided, but both stereo channels are mixed along with the ST's sound chip output for monitor speaker output. Sound chip output can also be sent to the stereo output jacks as well.

In stereo playback mode, the same data is regarded as words, with the high byte of the word being the sample for the left channel, and the low byte the right channel sample. In mono mode, each byte is output to both left and right stereo channels, but data is still fetched one word at a time. This means that mono sample data must always be an even number of bytes.

Samples are grouped together in frames. Each frame can be played once, or repeated automatically forever (until stopped). Two registers are loaded with the frame start and end address - the end address is actually the first byte beyond the end of the sample. Thus a 512 byte sample with a frame start address of 101024 would have a frame end address of 101536. Table One gives the location and description of each DMA sound register.

Actually playing a sample is really quite straightforward. Simply assemble the data in memory, load the start and end addresses, set stereo or mono mode and the playback frequency. Finally, write a one to the sound control register, and the sample will play once.

Producing continuous sound and linking frames together are the next steps, and hardware support is provided for these processes. The DMA sound chip produces a 'DMA sound active' signal which is connected to the external input of MFP Timer A. This signal is a one when samples are being played, and zero otherwise. At the end of a repeated frame, this line goes from one to zero, and then back to one again. Thus setting Timer A into event countdown mode allows you to generate an interrupt when a frame has been played a set number of times.

Frame repetition is seamless - there is no time delay between the end of a sample, and the start of it's replay, because the frame start and end registers are double buffered. Writing to these registers actually places the data into a holding area, and the contents of the holding area actually go into the true registers when the chip is idle (at the end of the frame, if one is currently being played).

Thus, if you wanted to play two consecutive frames, you would write the start and end addresses, and set the control register to three. The first frame will start playing, and you can immediately write the start and end addresses of the next frame, without waiting for the first frame

to finish. There will still be an interrupt from Timer A at the end of the first frame, and you could use that to load the address of a further frame, and so on.

One further thing to note is that the 'DMA sound active' signal is also exclusive-ORed with the 'monochrome monitor detect' signal, and fed into the GPIP I7 input of the MFP. This was provided to enable interrupt driven sound without using the last free timer of the MFP. It is a little more difficult to use, since you will get a different signal edge depending on whether a mono or colour monitor is attached, as well as an interrupt at the end of every frame.

Monochrome monitors ground the 'mono detect' line, resulting in a zero when the bit is read from the MFP. Colour monitors don't ground the line (it is left floating), and the bit reads one. When DMA sound is active, this situation is inverted (because of the XOR with the 'DMA sound active line'). TOS actually looks at this bit during vertical blank time, to see if the monitor has been changed, but TOS on any machine with the DMA sound chip has been appropriately modified to avoid problems.

Finally, the 'DMA sound active' line goes from active to idle (one to zero) after the last sample has been fetched. There is a four-word FIFO (First In, First Out) buffer inside the chip, so it will be eight sample times (in stereo mode) before the sound actually finishes. If you do not reload the frame registers in this time, then the join between samples will not be seamless.

The volume and tone controller of the STE is connected via a MICROWIRE bus interface. The idea behind this is that further devices can be added to the bus in the future. The MICROWIRE bus is a simple three wire serial connection, with a protocol to allow multiple devices to be controlled individually.

In the general case, the data stream consists of N address bits, followed by zero or more don't care bits, and then M bits of data. The actual hardware interface in the STE consists of two 16 bit read/write registers, one for the data to be shifted out, and a mask indicating which bits are valid.

A one in any bit of the mask indicates that the corresponding bit in the data register is valid. Data transmission starts as soon as the data register has been written to, so the mask register must be loaded first. Sending takes approximately sixteen micro-seconds, and if the data register is read during this time, a 'snap-shot' of the data being shifted out will be obtained. This means that if you wait for either register to return to its original state, you can be sure that sending has been completed.

The volume/tone controller is addressed by a two bit address field of %10 (binary) and a nine bit data field. Table One details the commands that can be sent to the device, and the addresses of the MICROWIRE

registers in the STEs memory map. Actually sending these commands is easier than it looks. Simply set the mask register to $07FF, and place the data in the lower nine bits with %10 in the upper two bits.

For example, setting the mask to $07FF and the data register to $04C4 will set the master volume to $14. That's all there is to it!

Regards,

Mathew Lodge

Video Harware Modifications
===========================

Addr Access Size Use
====== ====== ==== ==
FF8204 R/W 6 Video address counter (high)
FF8206 R/W 8 Video address counter (middle)
FF8208 R/W 8 Video address counter (low)
The change here is that these registers are now
read and write, allowing the programmer to
update the video refresh address to any word
boundary _at any time_.

FF820C R/W 8 Video base address (low) (VBASELO) This register
didn't exist on the ST, but on the STE it allows
the positioning of the screen base address on
any _WORD_ boundary

FF820E ?? 8 Line offset (LINEWID) - the number of extra words
added to the address counter at the end of each
line, _MINUS ONE DATA FETCH_. This allows for
virtual screens that are wider than the actual
screen display. Clearing this register means the
STE acts like an ordinary ST.

FF8240 to FF825E Colour palette
There are now four bits for each of the red,
green and blue components. To give backward
compatibility with the ST, the least significant
bit is above the most significant bit. Thus the
register layout is as follows:

xxxx 0321 0321 0321; x=don't care
RED GRN BLUE

FF8264 ?? 4 Horizontal bit-wise scroll (HSCROLL). Allows the
start of each line to be delayed by 0-15 bits,
thus giving instant horizontal scrolling.

Horizontal fine scrolling isn't quite as trivial as it looks. The pixel offset
is loaded into HSCROLL, and the documentation then says the following about
the LINEWID register :

"If you are actively scrolling (HSCROLL<>0), this register should
contain the additional width of the display line _minus one data fetch_
(in low resolution one data fetch would be four words, one word for
monchrome etc.)"

The reason for the extra data fetch becomes clearer if you think about
what is actually happening. If you fine scroll by n bits, then n bits
are effectively missed off the left hand edge of the screen. But to get
a complete line of pixels, n bits must be added to the right hand side
of the screen. This constitues one extra data fetch for the display
processor beyond the usual requirement.

For example, if you had three low resolution pictures side by side in
memory, and you wanted to scroll across them, you would set LINEWID to
160 when HSCROLL=0 (no extra data fetch). When HSCROLL<>0, LINEWID would
be set to 156 (four less due to the extra data fetch done automatically
by the display processor).

Vertical scrolling is trivial - simply set the video address base to the
required address at horizontal blanking time.

That's all folks - for now - more info on the new controller ports soon.

STE CONTROLLER PORTS

Address Usage Description
==
FF9200 xxxx xxxx xxxx 3210 Fire buttons
FF9202 UDLR UDLR UDLR UDLR Joystick directions
Joy3 Joy2 Joy1 Joy0

FF9210 xxxx xxxx NNNN NNNN Paddle 0 X
FF9212 xxxx xxxx NNNN NNNN Paddle 0 Y
FF9214 xxxx xxxx NNNN NNNN Paddle 1 X
FF9216 xxxx xxxx NNNN NNNN Paddle 1 Y

FF9220 xxxx xxNN NNNN NNNN Light pen/gun X
FF9222 xxxx xxNN NNNN NNNN Light pen/gun Y

Four new joystick ports were added, directly interfaced to the 68000 bus, rather than using another IKBD controller. The table above gives the locations of the hardware registers for the joysticks, paddles and light gun/pen inputs. Note that the joystick registers are bidirectional, and can therefore be written as well as read. If the registers are written, then the outputs are driven until the registers are read again.

Two paddle controllers can be connected with eight bit resolution on each axis, and the current position of each of the four paddles are reported in the registers shown in the table. No information is given in the data sheets as to the voltage range that the A/D converters function in, but I would guess that it is 0-5V. The triggers on the paddles are bits zero and one of $FF9202 (Joystick 0 left and right.)

The light gun/pen position is reported in $FF9220 and $FF9222. The x-axis accuracy is four pixels in low resolution, eight pixels in medium res., and sixteen pixels in high resolution. The y-axis position is accurate to within one pixel in all modes. The x position only ranges from 0 to 319, and therefore must be left shifted for other screen modes. Again, no electrical information is provided on how to implement a light gun/pen.

1370. Solution to the bombs

Newsgroup: comp.sys.atari.st.tech
Date: 1991-02-13 12:16:19 UTC
From: avgroeni@cs.ruu.nl
Message-ID: <4837@ruuinf.cs.ruu.nl>
Source record: 49056

To everybody who owns a 1024 ST^e:

A couple of people answered my previous letter `bombs on an STE';
They all give the suspicion various desk accessories of the type
`control panel' (MDISK; JAMES...) are the cause of the problem.
I haven't yet done any analytic analysis to prove our suspicion;
suggestions are of course welcome (in particular suggestions on
what exactly it is in these DA's that causes TOS to be so nervous
about write protected or not inserted disks.)

I suppose these problems have been solved in TOS 1.64,
so ATARI, be kind and send every STE owner the new ROMS,
without asking such incredibly large amounts of money.

So far the ATARI bug class,

Annius Groenink

>(2) If I'm running emacs from a command line, how do I tell it where the
>home directory is (for emacs startup, etc).

Check the manual for the command line options. As far as I remember it's
-d or -D to load a specified startup file, like
emacs filename -d/emacs/emacs.rc
Try to set the HOME env variable with your command shell, this might
also work.

Talking about programming environment, I heavily use the Okami Shell
rather than Gulam or any other shell since it can do a lot more.
In the Okami Shell, you would have to type
HOME=/emacs
export HOME
or put these lines in your profile to change the home directory. Gulam
should require a command like setenv HOME or the like.

1372. Help EPROMs needed...

Can anyone out there give me an idea of US prices for 32k*8, 35ns EPROMs?
Any names and addresses of relevant companies would be welcome too.
They're about $200 apiece here!

Smaller ones could be used, but I'd like to keep the speed up...

Replies by email preferred, Thanks in advance,

Marcus Bointon.

I remember having this problem for some time on a TOS 1.2 1040ST. The
reason for this was an auto folder program which was supposed to speed
up disk access (as far as I remember). Boot your system without installing
anything from the auto folder and see if the problem is still there. If
it's not, activate the auto folder prg one by one to see which is to blame.

1374. In the mean time, NO MAC ROMS

I am interested in purchasing a SPECTRE cartridge but I have been unable to find a set of MAC ROMS. They are indeed very scarce. Several places I have called have been out of stock for weeks.

Can anyone direct me to a source for the MAC ROMS? I can tell you a dozen places that have had them in the past but do you know of any at the moment??

Having spoken to Gadgets personnel, there attitude is that they are not concerned because they have a backlog of orders anyway. They could not offer any definitive source nor did it mattered to them because they are backlogged anyway. Simply a bad attitude!

Nutek's clone of the MAC system is not a near term solution to this problem maybe not a solution at all. In the mean time Gadgets by Small should maintain an up to date list of suppliers for the ROMS as a service to their potential customers.

One suggestion; didn't someone say that Supercharger pretends that the
ST mouse is a Microsoft serial mouse on COM1? If so, try setting Procomm
to use COM2, it might work.

Maybe they can't find them either, unfortunately.

I remember when Dave Small was asked about the availability of Mac ROMs, he seemed so confident that they would be available for months after Apple's decision to stop distributing them and after they canned Denny Hayes. It's a good thing he's starting up on the 68030 stuff.

Hey, I think I get it on my (homebrew connector) Tandy drive B with my ancient 520ST ('85 vintage) - it doesn't happen on drive A. No idea why - would love to fix it.

I also have similar request. I recently got Spectre GCR - well, I got it before the ROM shortage 8-) and I have a mouse crashing problem. I ended up trashing my system 6.05 disks on version 2.65c of Spectre. Turns out that they're not compatible - and I didn't know it - or make backups from the Spectre menu until too late. I had assumed that the mouse crashes were due to the previously trashed and not properly installed system driver. However, I get the same problem currently running Spectre 3.0, which supports sys 6.05. I found this out when I realized that I could boot from the disk utility disk. Since I'm getting a fresh copy of everything from a local mac store soon, I want to fix this (Rats, first the NEC drive to fix, then this!).

The symptom is that the mouse freezes on the screen, and I then trash my system disk, since the keyboard is not responding either, and mac menus don't have default key equivalents anyway 8-(. Do I need a new IKBD processor, or a new machine? If only TTs were class B approved! This risky store-in-memory behavior of the mac file system is souring me on the whole deal. I know, Un*x also can crash horribly when it loses power - but at least *it* has fsck! A "busy or defective" app on a mac does not seem to be fixed by the disk repair program (humph!).

Try not running any accessories, and see if the problem goes away.

There is a bug in some TOSes: if an alert comes up, and then an accessory's event_timer call expires, and then the accessory makes a GEMDOS call, you will get bombs when you click either button of the alert.

The original Control Panel from Atari (the one that lets you set the colors) did in fact use event_timer and then make GEMDOS calls, so it would cause this problem to happen.

Most accessories don't have this problem, since (A) they don't use event_timer much, or (B) they don't do GEMDOS calls as a result of event_timer.

nico@cs.ruu.nl (Nico Verwer) writes:
>about all [the SLM804] can do is print bitmaps, which are built in memory.

That's right. But the WAY it prints bitmaps, and the way they are built,
and the way they get sent via DMA to the printer, are all pretty strange.

One thing you can do is have your program (whatever it is) write a page
image to memory, then use the DIAB630 software to send that page to the
printer. There are escape codes which say, "Hey, printer driver! There's a
page image at location X in memory - print it!"

So if you can get a bitmap to appear in memory someplace, you can point
DIAB630 at it and it'll be printed.

>them) and has a list price of $169. The minimum configuration
>you will need to run all of the utilities is a 1 meg machine and
>you should have 2.5 meg (or better) with two double sided floppy
>drives.

Yes, i know, minix is a great programming environment -- but you need to say
that minix != tos, so all you can write are minix == unix programs!

Now you know what i use when i am writing unix programs ...

When programming in tos (in my setup all graphical programs etc.) i use
the cc wrapper supplied by the compiler (how about the TurboC one :-)).
I finish it with the PD make as found in all the atari archives.
The rules part needs a bit of tweeking for all compilers, but this is not
too difficult (But i ended up with five makes: MWC, MEGAMAX, TurboC + GPshell,
TurboC + Gulam, Sozobon)

Note that my rule for ld, the loader, for TurboC involves calling a program
which produces a .lnk file -- TurboC does not understand more than 126
characters on the command line.

If you know someone with a REAL Mac, have them install key
equivalents into the Finder resources with Resedit. That may help
that problem. Also, the "busy or defective" error is usually automatically
reset by my Mac SE when I reboot, since it knows that the program cannot
be busy. The 'Busy' bit can also be reset with Resedit or a Mac DA called
DeskZap which I use a lot. I have crashed my Mac a lot and have never
trashed the system files or any of the program files. I just reboot and
continue on. I have lost work in progress though. For slightly buggy programs
like DMCS ver 2.0, I use an autosave DA so I don't lose too much when it
crashes (it doesn't handle MIDI active sensing very well).

Hi, I've recently got hold of this Seagate ST157N SCSI disk drive,
and would like to connect it to my ICD Host adapter, unfortunately
I do not have any strapping info for it, would anyone who do have
this information care to mail it to me?

Thanx a lot in advance!

Owe.

1384. Re: PC Ditto II booting from Hard Disk

Newsgroup: comp.sys.atari.st.tech
Date: 1991-02-14 15:36:24 UTC
From: bcc@Eyring.COM
Message-ID: <1991Feb14.153624.11473@Eyring.COM>
Source record: 49069

Many thanks to those who responded to my questions about booting PC Ditto II from my hard disk. Some suggested that I needed to use the AHDFIX utility to properly use the Atari hard disk drive. Unfortunately (or fortunately, depending on point of view) I am using a Syquest drive with an ICD controller, and the PCD documentation indicates AHDFIX is only needed with the Atari controller. (I tried it anyway, it didn't work.) Someone indicated I only needed to use the utility PCDFIX, but before I could run that one down I found that:

1. I have to use MS-DOS 3.3. I had been trying 3.1 and the two looked at the disk in different ways.
2. The driver from pc ditto must be installed in config.sys.
3. The disk must have been formatted by MS-DOS with the format C:/S command.

With this done, everything seems to work. One minor bug remains; I cannot format partition D:, the format utility objects strenuously. I don't remember about D, but if I try to access some partitions, I get garbage in the files. C works fine, but J and so forth don't co-exist well between MS-DOS and TOS. Some final questions:

Has anyone had success sharing all partitions in common between MS-DOS and GEM?
What is PCDFIX, where is it, and what does it do?
Is there any way to have PCDII allow type-ahead at the keyboard? Anything I type when it is not waiting for input seems to get lost.
The serial port doesn't seem reliable. I tried running Kermit and have heard others complain about procomm, etc. not working. Is this a limitation?
Curiosity prompts me to ask, are the other emulators (Supercharger, ATSPEED, and the other one from Michtron (sorry, forgot!)) better in the points I mentioned?
Thanks to one and all! Brian Cooper

Excuse my ignorance, but what *is* a "cc wrapper"? I can only think
of the environment variable CC that is set up sometimes in make files.
As for posting it - sure if it's useful, I'd like it and a make for
Lattice C 5.06 (they don't give you a make!).

Get the PRO GEM series of articles by Tim Oren. Pro GEM is a collection of 17 tutorials on GEM programming and if you find a complete set they should also include the associated example C source code files. Included in the source code is the code for the form_do() function in complete detail. You could modify it to meet your needs. This is all in the public domain and available through good BBSs, some network nodes, Compuserve and GEnie.

Source record: 49100

I have posted twice in regards to how do you convert the DMA port to
SCSI configuration. So far no one has given even a hint as to how to do it.
All that I have been told is to go and by either an ICD or BMS200 host
adapter. I'm sorry to say that I am a technical junkie. I would really like
to know. It seems ridiculous that I can find out how an ST506 is connected
and operating on a PC, a SCSI drive is connected and operating on a SUN,
on an AMIGA and on a MAC. BUT no where can I get info for the ST. Is this a
deep dark secret, is it labeled as 'EYES ONLY', WHAT GIVES ??

If this info is non-disclosure material then say so and I'll quit asking,
but if it isn't then why wont anyone offer me some advice. Yes there are
still a few who are willing to build there own hardware addons.

Thanks in advance.

The ACSI-to-SCSI board that's inside a Megafile (60, 44, etc) expects BOTH SCSI DRIVES TO BE UNIT 0. And, as you found out, you have to change one of the DIP switches to enable the second unit.

I *did* port this! I mailed it to the moderator of
comp.[sources/binaries].atari.st, but nothing's happened yet. I haven't
even gotten a confirmation. Did I do something wrong? What is the
official way to submit something for posting?

I also posted it to atari.archive, but people using BART know you can't get
there from here any more. I don't know about the rest of the world -- is
that archive still available via FTP? Would somebody with FTP access check
for me? I did get confirmation from the folks who run that show. The
files should be called RCS5AP1S.LZH and RCS5AP1B.LZH for source and binary.
Also DIFF115S.LZH, or something like that, since I had to release the
source to my port of GNU diff version 1.15.

Be careful, RCS is an overloaded acronym. I'm pretty sure that the RCS
mentioned in the first context is Revision Control System.

Did Bob mean this or some sort of Resource Construction Set?

Since I can't access GEnie, I can't check.

I've been offered two 256K simms (spec to follow) from a Mac Plus. What I want to know is whether I can fit them to my 520Ste (it does have simm sockets) and whether they will work or not. The specs for the Mac simms are as follows..... 25{ K * 8 (256K * 8), 150ns.

Thanks in advance.

of bussiness). I am not sure how far the copy right law can go, may be they try to avoid been tie to the sell of ROM by Apple.
Their service might not be perfect, but not that bad compare to many company that made software or hardware (not only ST but also IBM, Mac).
I have no connection with them except I have been happy user of Mac emulator ever since the Magic Sac to the GCR 3.0 at this moment. To me, they do not seems to have much time in answering every question individually, (yes, they did not answer individually to most my question), but Mr. Small do answer quite a few question on the newsgroup in summary. (The SST is one example).
Nothing personal. They have done a good job in produce a soild good product for us, and the news letter they send has a lot of informations in it. And the update has been very good.

Hmmm. Seems like I started a productive thread! Vive la diff...

Well, I've got Gulam (*07) & GnuMake (3.58) & Turbo-C working together pretty well. Every now and then I get some kind of bomb (I suspect Gulam & Make interactions, maybe it's something odd about TOS 2.05) during the exit of one of the TC programs. Seems to work adequately. I wouldn't mind something more bullet-proof though.

I'm told that GPShell (part of the Craft development package), marketed by CoMedia of Amsterdam, Holland is a "solid" product. Includes a built in make, a shell script language, file completion, pipes, redirects, etc. Question of the day is: Is this still available? Anyone know more about it?

Thanx for the help and advice I've gotten thus far from the Net Gang!

1397. MIDI (continued)

Newsgroup: comp.sys.atari.st.tech
Date: 1991-02-15 17:43:15 UTC
From: miskinis@aisg.enet.dec.com
Message-ID: <3979@ryn.mro4.dec.com>
Source record: 49083

Hello,

I've received numerous replies from people on the USENET who I
wish to thank for their time and effort...

Perhaps I should have stated up front exactly what I have done
in the past 2 years leading up to my recent postings, the documentation I
have purchased, etc..

I've been an Atari customer for several years, beginning with their
8-bit line, and then "blowb away" with the capabilities of the ST, which
I had to have right away, for it's graphics and MIDI architecture.

I began developing a sequencer shell, orginally in Pascal, and
later ported to C. All coding was done in "C", and MIDI I/O was performed
exclusively via the BIOS and XBIOS functions. The exclusion was a timer
routine that ran in the backgound, thus providing me with a timestamping
metric. Each byte had a time stamp as to when it came in relative to the
beginning of the sequence. And you know what? It worked perfectly (so
I thought). I had musician friends over now and then, who were amazed
at the accuracy of a "home grown" application, and were frustrated that
they could not crash the program by wiggling the bender, stepping on the
pedals, and placing their entire forearm on the keys.

I had a 5-octave keyboard on the screen, lighting a rectangle in
each key when it was "on", and unlighting it when it was "off". Once
or twice a month I then noticed that a key would remain on, when it's
midi note value was specifically turned off. I then questioned the validity
of my earilier recordings, and proved a few of them invalid by using a non
decaying synth sound. I had earilier used piano sounds, which would decay
ANYWAY, whether or not a not off message was ever received!

SO, then I started experimenting, and removed ALL code except what
was need to record a byte from the MIDI port each time it came in. I even
eliminated the background timer to be sure that it was not interferring.

I wrote routine that would scan my data, looking for corruption.
I noticed that when a byte was WRONG, it was a copy of the last on, and
one was missing (the interrupt fired, but the previuos byte was still in
the ACIA buffer.

I then learned 6800 assembler, and wrote a routine that emulated the
BIOS MIDI functions, and had the EXACT SAME PROBLEM. I then added code to
check the ACIA status, and found that there were overruns. I had been using
the KBD vector MIDISYS to point to my interrupt routine, which is really
only as good as the routine that IT is called from, being the standard
level 6 interrupt handler, which handles keyboard, mouse, and MIDI I/O.

I currently have "The Tackle Box" (~900 pages containing the full docs for the 68000, 6850, etc.), Mark Williams C, The Abacaus Atari ST Internals book, the Sybex Programmer's guide to GEM, and various magazines.

I want to overcome the problems with the current interrupt structure of the ST, and if I have to write my own code to handle the mouse and keyboard as well as MIDI, I don't mind doing that. That way I can control the priority of the devices, and not spend time handling the mouse or keyboard when it would effect MIDI I/O that I deem the most important task in recording.

I ask that you Post instead of replying by mail, so everyone can benefit from this invaluable discussion. There is little or no other source of public information that I cam aware of. If there is, LET ME KNOW!

Thanks, and Atari Forever!

John (sick with the flu, pardon my rambling in some spots)

I'm the author of Tuneup, such as it is. (Though not of its documentation.)
A version does exist that should handle "big" partitions, though it's never
gotten any testing (that I know of) beyond local people. It was sent many
months ago to Michtron for more general testing & release, but I've haven't
heard anything since then.

I also have no idea as to what its current status is since the
sale of Michtron to that New Jersey firm. As I said above, I haven't
heard anything from Michtron/etc. in many months. I don't even know
how to contact the New Jersey company that supposedly bought Michtron.

If it was definitely clear that I legally could do so, I would be
willing to give "special" updates (with the understanding that this
version has not been as extensively tested as previous versions.)
However I will not spend any money to get such a legal clarification.

> the entire thing into a card and not bother with the cart!).

I really don't think so. First of all the implementation is
not really ST accessable. Mainly because as so many other people
have pointed out it uses the Motif/X Release 4 interface which is
so large that you people would need 4 megs for just a good (complete)
implementation. And a 8Mhz 68000 running X is something I don't
want to think about using.

What it does do is open up the possiblility of Mac programs being
transportable to the mainframe world, perhaps with a little rewrite
here and there, Mac program could be running on the nearest super mini,
386/030 machine nearest you!

Really, the MAC ROM problem is quite a nasty problem. I have tried
to call gadgets inc many a time to cancel my order as:

Spectre GCR 299 + MAC ROMs 273 = ~600, another hundred I could get
a Mac Classic at dealer cost. And from what I here 273 is an excellent
price for the ROMS.

I am really steamed. Apple is engaging in guerilla warfare and
I am going to get my ROMS APPLE if I have to either BY THEM LEGALLY
or obtain them WITH OTHER MEANS at MY DISPOSAL.

I really wish more guys like Denis Hayes existed so that we could
REALLY give Apple some blows, economically. There is absolutely no
competition between Apple and other companies because Apple decided
everything Xerox Park worked on was actually theirs to use, and no one elses.
People are forced to buy Apple technology at premium prices. I think
the Supreme court should tell Apple that the technology to transform
Xerox Park's work should be PUBLIC DOMAIN, after all, look what happened
to AT&T. Now we have competition, we can actually use phone lines
now with 9600 baud modems because these companies worked to improve
their communications equipment.

---For a safer world, I would like to see thousands of people do what
Denis Hayes did, Apple would be forced to drop its shorts and eat'em.

Or how about an IIfx for 1800.00 bucks?

> of the environment variable CC that is set up sometimes in make files.

The idea of cc is to have one program that calls all the right programs (pre-processors, compiler passes, optimizers, linkers) in the right order with the right command lines.
Basically you set up cc so it 'knows' where to find your include files and your libraries (and the executables if they're not in the PATH). Then you just type for example:

```
cc -f aaa.c bbb.s ccc.o ddd.lib
```

instead of:

```
tcc $CFLAGS -Id:\tc\include\ aaa.c
mas $ASFLAGS bbb.c
tlink o=aaa.prg d:\tc\lib\tcstart.o aaa.o bbb.o ccc.o ddd.lib \
d:\tc\lib\tcfltlib.lib d:\tc\lib\tcstdlib.lib
```

ES> All that's missing is RCS, and Allan Pratt mentioned that he's working
ES> on porting this.

Allan told he would be working on RCS version 5. In the mean time I got RCS version 4.3 from somebody who got it from somebody else (The name of the proter must be somewhere in the files, but no address was included - I just forgot who it was, but it was a person in Groningen, the Netherlands).

I have put this version in our archive for those who can't wait for Allan.

How to get rcs.zoo from the archive at
Dept. of Computer Science, Utrecht University:

NOTE: In the following I have assumed your mail address is john@highbrow.edu.

Of course you must substitute your own address for this. This should be a valid internet or uucp address. For bitnet users name@host.BITNET usually works.

by FTP: (please restrict access to weekends or evening/night (i.e. between about 20.00 and 0900 UTC).

ftp archive.cs.ruu.nl [131.211.80.5]
user name: anonymous or ftp
password: your own email address (e.g. john@highbrow.edu)
cd /pub
don't forget to set binary mode if the file is a tar/arc/zoo archive, compressed or in any other way contains binary data.
get ATARI-ST/utils/rcs.zoo

by mail-server:

send the following message to
mail-server@cs.ruu.nl (or uunet!mcsun!hp4nl!ruuinf!mail-server):

begin
path john@highbrow.edu (PLEASE SUBSTITUTE *YOUR* ADDRESS)
send ATARI-ST/utils/rcs.zoo
end

NOTE: *** PLEASE USE VALID INTERNET ADDRESSES IF POSSIBLE. DO NOT USE ADDRESSES WITH ! and @ MIXED !!!! BITNETTERS USE USER@HOST.BITNET ***

The path command can be deleted if we receive a valid from address in your message. If this is the first time you use our mail server, we suggest you

first issue the request:
send HELP

SPICE = Simulation Program with Integrated Circuit Emphasis

It is an electronic circuit simulation program. You supply the "netlist"
and component parameters and it can calculate voltages/currents/waveforms/
power and many other behaviorial parameters of that circuit.

Very useful when you can't "breadboard" the circuit for some reason, or
if you want to test the circuit under conditions that might damage real
components. Also much easier to examine simulated waveform graphs than
to try to get the waveform on a scope (especially for transients)

brian@.Waterloo.NCR.COM (Brian W. Gamble) writes:

- QUESTION ONE
- Do you need to do anything special to get 1.44M out of it? I can't
- seem to get it to read a HD disk... I've found a SW/PD formatter
- called Diamond Format, which formats to 1.44M (or 1.6M if you use
- more sectors than usual). It also seems to be a stand-alone portion
- of a hard drive backup program. Do I need to find a special driver
- or something? The drive works fine as a double density...

There is a product called the PowerDrive. It comes in two parts: a
drive controller replacement and a 1.4meg drive. You can buy the
drive separately, but you must by the special controller from them.
I think it uses the faster WD1772 (is that the right part #?)
controller chip. The board itself costs $139.95. I think they
recommend a Teac drive.

A friend of mine has this installed on his 4meg STe. He says, not
only is the 1.44meg drive faster, but his external 720K Indus drive
jams. He says you can see on the track reading that it's much
faster. However, he adds that there is some incompatibility with
copy-protected games.

DreamPark Development
1390 So. 1100 E. Suite 104
Salt Lake City, Utah 84105
(801)-484-9809

- QUESTION TWO
- Does anyone know where I could find a 14 pin DIN (ie, the ST's external
- floppy drive port) plug adapter, that has a female 34-pin (ie, the
- floppy drive's bus) port on the other end? Or am I doomed to building
- one? Given the half-dozen or so 3rd party manufacturers of external
- drives for the ST, a part like this HAS to exist, right?

re: programming environments, etc....

I just recently downloaded Allan Pratt's port of RCS (Revision Control System) from GEnie (since I have no ftp access) and it's SWELL! This filled my last remaining major wish for programming tools on my ST. Thanks a bunch Allan!

My other programming tools are: gulam, which I love for it's pathname completion; Mark Williams C, which I find quite adequate for my purposes and the documentation is indispensable; MicroEmacs 3.10; and the make program that came with MWC. Plus I have a pile of tools like grep, awk, etc that came from various places. This all makes for a very pleasant programming environment on the ST.

>
>_John_ (sick with the flu, pardon my rambling in some spots)

You're exactly right that you're being bit by overruns. If any routine spends too long with interrupts disabled, or if you spend too long parsing mouse or keyboard packets (which is done at the same interrupt level as the midi handler) and a second byte comes in, you get an overrun condition, and one symptom of this with the default hanlder is a repeated character.

I will post a couple of programs here that demonstrate how easy it is to get this problem. One program blasts ordered data out the midi port on a transmit buffer empty interrupt, so the data goes out as fast as possible. The other, run on another machine, scans the received data and reports errors.

I sent these to Atari years ago asking for help, but I was smarter about the problem than anyone I could get in touch with there...

The solution for me was to diverge from standard midi format and write a packetized layered system that insures that the received data arrives error free. This obviously is not an option if you must talk to synths.

The problem should be solvable by rewriting the mouse and keyboard handlers, minimizing other interrupts and critical sections. Obviously this is a big job, so I wish you the best and let the world know when you find a solution! My test apps will be here soon...

> Spectre GCR 299 + MAC ROMs 273 = ~600, another hundred I could get
>a Mac Classic at dealer cost. And from what I here 273 is an excellent
>price for the ROMS.

Lets put some things aside:

1) I am as religious about my car, my favorite TV show and my Atari
ST as is the next person.
2) Disregarding that GBS has taken customers away from ST software
producers(granted there's not much), they do support their product
well.
3) Their product is well designed, reliable, very compatible.

Lets see Gadgets offer one small favor to their potential customers -
two or three MAC ROM suppliers that they know have had the chips
in stock within the week. Right now people are suggesting this source
or that, stating that yes I bought some there 5 months ago. The
problem of finding MAC ROM chips is hitting the fan.

For a few hundred more bucks, a complete MAC system is looking very
appealing compared to buying a Spectre GCR for which one has to buy
MAC ROM chips at between $200-$300 a set. A blank ROM chip is $3,
right? But first things first, give me a supplier so that choosing
between a Spectre GCR and a MAC is within the realm of possibilities!

>Is there a better way?

The shell_read() call returns the info you are looking for. Watch out
though. Apparently, some Shells (command line interpreters) do not set
things up properly - it will definately work from the desktop though.

1411. MIDI (one problem solved!)

Newsgroup: comp.sys.atari.st.tech
Date: 1991-02-17 23:30:56 UTC
From: miskinis@aisg.enet.dec.com
Message-ID: <3998@ryn.mro4.dec.com>
Source record: 49099

Hi,

It seems that the level 6 interrupt handler is at (hex) FC281C
accoring to a memory map I have. (I loaned it out, but have called in
all documentation I own!).

I have started writing the level 6 interrupt handler. I currently
look FIRST in the MIDI ACIA, and then the KEYBOARD ACIA. If I get a (hex)
61 (UNDO) I exit the program... Otherwise I display the contents of my
MIDI byte count, MIDI overrun count, MIDI buffer empty count continuously.

I tested it by attaching my TR505 drum machine to the ST, cranking
the tempo to full, and playing a pattern of several (simultaneous) drums on
16th notes. I HAVE NOT HAD AN OVERRUN YET!!! And upon exiting, I simply
call the MFPINT with FC281C, and the original level 6 interrupt handler
is reinstalled. Prior to this, the keyboard and mouse were inoperable
without a reboot every time I exited my program...

But, until I write code to handle the mouse and keyboard such that
they behave correctly, I can't develop a nice user interface...

I've compiled GCC 1.39 on my ST. I used the GULMAKE package that was created by Jim Hurley. It's a series of Gulam scripts that automates the make process. It takes about 2 or 3 hours to completely compile GCC and I experienced relatively few problems, though it's something I'd rather not do very often :-)

Kbdvbase() returns a pointer to a vector table pointing to routines
to handle midivec,midi over-run error handling as well as other routines.
All that needs to be deone is to replace the slow handler with your own
fast code, and stuff a pointer into the vector table.

> But, until I write code to handle the mouse and keyboard such that
>they behave correctly, I can't develop a nice user interface...

this may sound painfully simple (so simple it may not work - i have not
tried it), but maybe u could install your routine, so that is handles the
midi, then jumps to the old handler somehow. handle the midi yerself, let
the bios do its thing with mouse/keys/etc. you would need to "clear" any
midi event, so that the old handler never sees a midi event...

another idea is to disassemble the old code from memory loc u gave,
and fix it, calling it your own. or maybe just jump to the code which
does non-midi stuff.

am i nuts? (don't answer that :-)

1415. Incompetant sozobon-C programmer seeks time

Newsgroup: comp.sys.atari.st.tech
Date: 1991-02-18 07:32:26 UTC
From: macross@portia.Stanford.EDU
Message-ID: <1991Feb18.073226.23221@portia.Stanford.EDU>
Source record: 49102

Hi. I recently downloaded the Sozobon C compiler and dlibs library from panarthea, and while everything seems to go pretty smoothly, I'm having tons o' trouble with the routines in <time.h>.

In short, any call to ctime() gives me a two-bomb crash, and I can't seem to declare a pointer to type tm to use asctime() -- no matter what I include or what's extern, I get "struct tm undefined" compile-time error (and all the subsequent "undefined" errors).

I haven't done any serious C programming for a few years, so feel free to e-mail me any patronizing you might think of... it's probably right.

--Chris Adamson (macross@portia.stanford.edu)

P.S. FYI, I'm just trying to write a teeny-tiny little program to input the date and time via stdio and set the clock (w/out having to load the control panel or buy a clock card).

>deep dark secret, is it labeled as 'EYES ONLY', WHAT GIVES ??

Many of the informations you need for a ACSI/SCSI host adapter is
in the ACSI specifications from ATARI. If you're a registered developper,
you get a copy of them. I have written a (German) book on floppies
and harddisks, and the harddisk part might also clarify most of your
questions. The whole matter, however, is too complex to discuss it
thoroughly in this conference. Since the ST DMA bus is not very stable
all in all and its timings vary from revision to revision (remember
those IMP chips?), you're in for lots of trouble when designing
a host adapter of your own (trust me, I was partly involved in
the development of a new host adapter; it took about a year of
intensive testing before the damn thing worked reliably with any
ST they could get). Therefore, you were given the hint
to better forget it and get a commercial solution.

Source record: 49108

I would like to write a many ST game programme which links together n STs where n>=2. Could anyone give me a pointer as to how this could be done?

1. Would it need one ST used as a server to the rest?
2. Should I use the MIDI port as there should be a through connection?
3. I wouldn't mind making a simple bypass circuit for the serial port, this would require a simple interrupt programme that checked the serial port to see whether the computer should take the message on the serial port or should let it through to the next ST (This is beginning to sound like a LAN!!!)

Anyhow you get the idea

Hi,

Just to add my $.02 at this interesting subject.

I own a Mega ST1 with 2 drives (no HD). So it wasn't
easy to work with MWC (in ram disc for speed reasons).
Now, I've the whole stuff in a 500k ram disc.

I 'packiced' all the (other than text) files and all
the text (ASCII) files thru a filter that removes all
the (C) comments.

Unfortunatly, 'packice' doesn't works for all the non
ASCII files, so be warned and do this ONLY on a copy.

For exemple .ACC's and uniterm.prg (two that I just
have in mind) don't like to be 'packiced'.

I've to have also only small .ACC's.

I'm now waiting for the Mega STE (with 4 Megs)...

Regards

You need to buy a 1.44 meg disk controller board such as the one available
from DreamPark Development (the PowerDrive). The ST's floppy disk controller
WD1772 cannot handle high density format. Diamond Format, which is a
formatter distributed to the public and with Diamond Back II, was specifically
modified to format high density drives like the PowerDrive. Diamond Back II
also fully supports 1.44 meg drives in all program functions.

>done?
I've done this with a Multi-User Adventure game that I wrote. (Called Cantrip).
I was meant for use on unix hosts, but I ported it to the ST. You can connect
upto 20 machines together, (this is a #defined limit, so more could be
connected upto something like 64).

>1. Would it need one ST used as a server to the rest?
Thats the way I've done it. One machine runs the game, and the others act
as terminals (of a sort).
>2. Should I use the MIDI port as there should be a through connection?
I used Midi. But not the through option. You need to connect Midi out to
Midi in on the next machine in a loop, all the way round to the first machine
again.

>port or should let it through to the next ST (This is beginning to sound
>like a LAN!!!)
I developed a packet protocol suited to the task. Each machine has a unique
address, it extracts all packets addressed to it, echo-ing on all others
to the next machine in the loop. It can also insert a packet into the loop
when it needs to. Who generates packets, and when is defined as part of the
protocol.
There are a few of points to watch out for.
1. The standard io handlers can't cope with the kind of data flow rates you
can generate on the ring. Resulting in loss of characters.
2. Data can only flow in one direction. So it may take a while to pass a
message from one machine to another. This also means the only handshakeing that
can be done is to pass a message back round the other half of the loop.
(In case of errors, its useful to get machines to extract out any packets
which were sent by them. Otherwise they may go round the loop for ever}
3. If each machine reads an entire packet before it retransmits it, the baud
rate is divided by 2 for every machine in the loop. I cured this problem by
reading the packet header, and if the packet was not intended for that machine
starting to dump out the rest of the packet as it arrived.

>Anyhow you get the idea
>advaTHANKSnce
>Robin
Your welcome.
What kind of game did you have in mind ? Midi may not be fast enough for
arcade games, unless the amount of data to be sent is kept small.

Cantrip is not quite finished (I'm not happy with the NPC code). But if theres any interest in the ST version, I could post a set of binaries (it should run on any ST, single or multiplayer).
,Kenneth.

From: saj@chinet.chi.il.us
Message-ID: <1991Feb18.210757.20269@chinet.chi.il.us>
Source record: 49114

I have a ST296-N running off a BMS-200 host adapter on my ST. I have a Stacy-1 with a 20 M internal drive. I have a third ST with no hard drive. What I'd REALLY like to do is get a FA-ST tape drive from ICD, add a SCSI 3.5" hard drive and put that on the third ST. To make that worthwhile, it would sure be nice if I could somehow use the tape to backup all the hard disks. This is complicated by the fact that the existing drives use Atari's formatting and partitioning scheme, and driver software, while the tape would necessarily use ICD software and stuff. Is there a way I can get all my wishes? I suspect that it may be of general interest if someone can tell how to do this in detail.

Cross-posted to: comp.sys.atari.st,comp.sys.atari.8bit,comp.sys.atari.st.tech

Perhaps someone can answer these questions about Darek Mihocka's (Hope I got the spelling right...) 8-bit emulator Xformer?

1) What are the pinouts for the Xformer cable (to hook up the 8-bit's drive)?

2) How does Xformer handle input from the joysticks? Are all 4 of the 8 bit's joysticks supported? Are only two? Do they plug into the ST's Mouse and joystick port? How about the "Paddles"?

3) How well does it do with disk based copy protected games? Does the "virtual floppy support" (files on hard disk) support disk based copy protection?

4) How fast is it compared to a normal 8-bit?

5) Could someone post the source code for Xformer 2.55 to terminator (Darek said it's now PD and is on Genie, but I don't have an account there. Has it made it to Compu$erve, or anywhere else I can get it?

6) Has anyone tried M.U.L.E. or Seven Cities of Gold on it yet? If so, how did they work?

Thanks for any help,
---jb (jfbruno@rodan.acs.syr.edu)

Indeed, this is a very bad thing to do -- certainly it will fail big time
under MiNT, and probably under RTX and other systems (including, perhaps,
future versions of TOS).

There is an AES call that can get the program name if the program was
started from the desktop. If you were started from a shell that supports
the mwc/Atari extended argument passing conventions, the program name
is put in the environment after the variable ARGV=. Some C compilers
will automatically put this into argv[0] (gcc and mwc will).

Whoa! The Motif interface is not X! It's a user interface standard -- a
``look and feel.'' It's just a legal dodge to avoid Apple's lawyers.
Implementing Motif doesn't require adhering to the programming strategies
used on Unix workstations.

Geoworks Ensemble licensed Motif for its windowing system and related
applications designed for the 8088-era Intel-based PC clones. From all
accounts it's small, fast, and what PC GEM should have been.

1429. STE - medium rez booting

Newsgroup: comp.sys.atari.st.tech
Date: 1991-02-19 16:56:48 UTC
From: jharres@sleepy.bmd.trw.com
Message-ID: <1192.27c0f660@sleepy.bmd.trw.com>
Source record: 49116

I just got my STE and per the suggestions on here I opened the DESKTOP.INF
to change the 12 to a 13 on the 5th line. However, there wasn't a 12 on the
line. It had a 2 as it's 3rd character. So I changed it to a 3. Now when
I boot I get MED rez as the original fix was to do. Why the difference (
between 12 and 2)? TOS vers 1.6

1430. TSR programs

Newsgroup: comp.sys.atari.st.tech
Date: 1991-02-19 17:11:33 UTC
From: csual@warwick.ac.uk
Message-ID: <M%~&|P|@warwick.ac.uk>
Source record: 49117

I recently started playing around with the Atari-specific libraries of Lattice C V.5, rather than just plain old bog-standard C. I've sussed out desktop accessories (I hope!!) but I don't even know where to start with TSR's.
Say I wanted a process to sleep until I pressed a certain hot-key, or some other such event like a timeout, and then wake up and do something. What do I have to do to set this up?
If you can help I'd appreciate it, and a simple TSR source (e.g. a screen saver) would be ideal.

Answers on the back of a postcard to:

jas@uk.ac.warwick.cs

Thanks,
Jason Morris.

1431. MIDI - A continuing discussion

Newsgroup: comp.sys.atari.st.tech
Date: 1991-02-19 17:33:30 UTC
From: miskinis@aisg.enet.dec.com
Message-ID: <4009@ryn.mro4.dec.com>
Source record: 49120

Hi,

In regard to the KBVBASE pointers:

Early in my efforts, I replaced the MIDISYS vector, with
my handler. I still lost bytes when the mouse was moved (when MIDI
input was coming in *FAST*).

I (just last night) attempted to jump to the standard keyboard
handler, after checking for MIDI data. I was unsuccessful...

I now have a routine that I install as the level 6 interrupt
vector. I check for MIDI first, then keyboard/mouse. I get no overruns
or ANY errors, but the keyboard and mouse are unusable until I exit
my program, at which time I deposit the address of the original level
6 interrupt handler back into the table.

I will be disassembling and analyzing the default behavior
for mouse and keyboard, and hopefullt producing a routine that will
handle everything witout any data loss.

ANY and ALL support is geatly appreciated!

John (almost better from the flu)

Message-ID: <rjwalsh.666992938@unix2.tcd.ie>
Source record: 49131
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

I have noticed at the beginning of an executable program file that there is a branch into the main program, followed by a
few numbers, followed by the main object file. What are these numbers? I have used the compiler supplied with STOS to write some
small routines for use in STOS; I would also like to use these outside it. These do not have the header that executable files have.
What info should I put before them to make them executable?
Also: could somebody give me a list of commands for directly turning on the Disk Drive, moving the head to a sector, reading
and writing a block to a sector, formatting a sector etc. I know the addresses $FF86xx are involved in this, but I'm not sure how.

Any info on both of the above would be appreciated.

1434. Re: Programming environments

Newsgroup: comp.sys.atari.st.tech

On yet another environment front, is there something that will "modify" GEM or otherwise provide a default font other than the standard? I'd like Emacs 3.10, GEM text windows (read Gulam), etc to have a nice, readable, eye saving font. The editor for Turbo-C (and in general) has many font's that it uses and while not perfect on a color monitor - they are quite pleasing.

The only things I can think of is perhaps G*Dos (but I'm a new guy and wouldn't know about this yet).

Having written my first TOS/MIDI program, I got burned in a big way (okay, it was only 2/3 of an hour) by trying to find out why fopen(..., "r") wouldn't read my data files (unsigned ascii). Seems that fopen(..., "rb") is the answer (for TC). Live and learn (it ain't unix). :-).

From: Bobster@cup.portal.com
Message-ID: <39432@cup.portal.com>
Source record: 49130

Just a thought, but you might be interested in my train of thought.

A file is executed by the following:

```
pea env Enviroment
pea com Comand Line Address
pea fil file name address (What you want)
move.w #0,-(sp) Load and Start (Execute the file)
move.w #$4b,-(sp) Function number
trap #1 (Call gemdos)
add.l #16,sp correct the stack
With this in mind, all you should have to do is the followin
```

```
sub #4,sp (Subtract 4 from the stack pointer and you should be pointing
at the address of the file name. (This could be -8 instead of 4))
movea (sp)+,a0 (Move the file name address into a0)
Now all you need to do is start reading at that address until you hit a
0 (End of file name marker) and you will have the file name the original
program used. (I think this will work in all situations. Be sure to not
mess with the stack before you do this though. It will probably need to be
the first thing you do. Oh and dont forget to correct the stack when you
done.)
```

```
I am not 100% I have this correct, but I am sure someone will tell me if I am
at error... ;^)
```

I hope this helps a little.

1436. communications software with VT100 emulation

- changed it to a 3. Now when I boot I get MED rez as the original fix
- was to do. Why the difference (between 12 and 2)? TOS vers 1.6

Okay, here's the beginning of my DESKTOP.INF file.

```
#Z 01 C:\AUTO\NEODESK3\NEOLOAD.PRG@
#a060000
#b000000
#c???000?000<000?00;;400;0;;;4440??0;;?0?;0;;;0??03111103
#d
#E 90 13
#W 00 0D 02 01 1E 15 00 @
#W 00 00 00 0C 15 09 00 @
[stuff deleted]
```

Minus the first line, which tells TOS to boot NeoDesk, the fifth line down reads #E 90 13 and before I changed it, it read #E 90 12. Actually, the 1 has to do with something else, but I thought mentioning 12 was a better idea than just 2 since some of the other values could also have been 2. To tell you the truth, I have no idea why yours was just 2 as the third character. I'd just say, as long as it works, don't worry about it. ;^)

There is a program called FONTRIX, I think, from Charles F. Johnson which will do this. I don't know if it's PD, Shareware, or if it comes on the Codehead Utilities Disk. A program called FONTLOAD came with NeoDesk 3 which lets you change the font. I can't remember the name of the font I have loaded, but I like it better than the default font.

From what I know, there are several packages out there. FLASH has a VT100 emulator, but I don't use it (I think it is incomplete); I do, however, use the VT52 (default), and I can vi on it (I don't know if this is a VT52 function, since the ATARI VT52 application does not allow me to do so.) HABACOM also has an (incomplete) VT100 emulator; I have not tried it yet, so I cannot say if it's buggy or not (although I soon will, so if need be I'll follow up). I don't think INTERLINK has a VT100. ATARI itself sells a VT100 emulator (20 or 30 bucks) -- you can even get it at your local FEDERATED! :-) I cannot vouch for K.I.S.S.
That's all I know, except I've had no problems with FLASH or INTERLINK set on VT52 for basic terminal functions. Good luck...

1442. SH204 Hard Drive problem

Newsgroup: comp.sys.atari.st.tech
Date: 1991-02-20 18:12:42 UTC
From: scoile@gmuvax2.gmu.edu
Message-ID: <3528@gmuvax2.gmu.edu>
Source record: 49121
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

I recently acquired a used Atari, SH204 hard drive, which I'm having problems with. I was wondering if anyone has had similar problems, or perhaps if anyone knows right off what may be causing the problem.

Occasionally, uppon boot-up, my SH205 will not recognize the 204 (the SH205 is physical unit 0, the SH204 unit 1). I normally give unit 0 a good head start on power-up (until the busy light flashes), and wait a good amount of time (10-15 seconds) for the 204 to get up to speed. Still, sometimes the 204 isn't recognized.

Next, (again, occasionally) the SH204 will spontaniously fail. It will just all-of-a-sudden, out of the blue, stop working. TOS can't access it (and yes, it IS still on...sheesh! :)

Any help will be greatly appreciated. Specs below:

Atari 1040STF
1 megabyte of memory (standard)
TOS version 1.0
Atari SH205 hard drive (unit 0)
Atari SH204 hard drive (unit 1)
AHDI 3.01

If you want to do DEC terminal emulation, run, don't walk, and grab a copy of Uniterm. The latest version that I have is V20.e 011. It emulates all DEC terminals from the VT52 through a VT200. It includes TEK4010 graphics and the file transfer protocols XMODEM and KERMIT. I have used various versions of Uniterm for 4 years now, and I have had nothing but good experiences with it. The only things that I have noticed that it doesn't handle are the save and restore cursor functions. And to top it all off, you get this very professional package as freeware. You should be able to get a copy by anonymous ftp from "atari.archive.umich.edu".

There are at least three ways. In increasing order of complexity (and
desireability):
(1) sit in a for(;;) loop, checking the time and Syield()'ing until
the time is up. The Syield's improve the performance, but you
still end up hogging a far amount of time
(2) use Fselect(x, 0L, 0L, 0L) (I think that's right -- I don't have
the docs here). That sleeps for "x" milliseconds, x <= 32768;
for longer waits, repeat as necessary. This is how the sleep()
function is implemented in mntlib.
(3) use Psignal() to set up a handler for SIGALRM, then use Talarm() to
set an alarm for "n" seconds away, then Pause() to wait for the alarm
signal to wake you up. This is the way it's usually done under Unix,
and is definitely the best way to do it (I didn't in mntlib because
I'm lazy -- doing it "right" requires checking to see how much time
you actually slept, because you might have been woken up by a different
signal; also, you have to watch out if there are other calls to Talarm()).

PS: Don't worry about harassing me; we hosers have to stick together :-).

Hi Bart and Brian,
I personally would recommend the VT100 emulator that comes with
Interlink. I have used many other VT100 emulations on the ST, but none of them
come close to the VT100/ANSI emulation that Interlink provides. It handles
color ANSI flawlessly, of course only in four colors because of the ST's
medium resolution. Interlink should be available at your local Atari dealer.

1452. How do I upload formatted txt

Newsgroup: comp.sys.atari.st.tech
Date: 1991-02-21 12:41:57 UTC
From: pdel@ADS.COM
Message-ID: <Z&`&1}=@ads.com>
Source record: 49133

Hello, I've run into a problem trying to upload a 1st Word document
to my Unix machine at work.

It doesn't look like you can transfer something like this which has
formatting characters in it.

This particular doc looks like this:

Hi^^Mom^^how^^are^^you^^hope^^everything's^^going^^okay^^sure^^am^^having^^fun

I assume all the ^^ chars are messing up the transfer.
I think I have all the port settings right because I tried transferring
some other text docs with no problem.

I tried doing this under gulam, as well as some other terminal prgs,
but no luck.

Any ideas/help is much appreciated.

Thanks, Peter D.

1453. TSR programs

Newsgroup: comp.sys.atari.st.tech
Date: 1991-02-21 15:02:28 UTC
From: csual@warwick.ac.uk
Message-ID: <N+`&HH-@warwick.ac.uk>
Source record: 48994

This is a second posting as I got no replies last time : Surely SOMEONE out there can help me. Pretty Please... 8-).

I recently started playing around with the Atari-specific libraries of Lattice C V.5, rather than just plain old bog-standard C. I've sussed out desktop accessories (I hope!!) but I don't even know where to start with TSR's.
Say I wanted a process to sleep until I pressed a certain hot-key, or some other such event like a timeout, and then wake up and do something. What do I have to do to set this up?
If you can help I'd appreciate it, and a simple TSR source (e.g. a screen saver) would be ideal.

Answers on the back of a postcard to:

jas@uk.ac.warwick.cs

Thanks,
Jason Morris.

>to change the 12 to a 13 on the 5th line. However, there wasn't a 12 on the
>line. It had a 2 as it's 3rd character. So I changed it to a 3. Now when
>I boot I get MED rez as the original fix was to do. Why the difference (
>between 12 and 2)? TOS vers 1.6

Well, I found out the cause of the difference mentioned above but not the
reason. I was changing the DESKTOP.INF file from my 1040 ST (with TOS 1.0)

ST line 5 => #E 9B 02
STE line 5 => #E 99 12

Anyone know what the changes to the STE DESKTOP.INF line 5 are for?

>Bill Shroka
>bjsjr@NCoast.ORG
>ncoast!bjsjr@usenet.INS.CWRU.Edu

As Bill says, this is a tedious process on the ST, but it is doable.
The only problems I have ever encountered were occasional 'make'
errors, or maybe gulam-make interaction errors. However, re-executing the
'make' picked up right where it left off.

So far, I haven't had any problems compiling or porting the GNU software,
(with the exception of 'less'), but you will probably need 4Mbytes and
a 32Meg HD partition (to store all the source in one directory). Thanks
to J. Bammi, et al, and their excellent gnulibs.

Another error comes to mind now - the version 1.37 'ar' aborts when it
tries to rename the final library archive, but it was built OK and you
can manually rename it. This was fixed in a later release of the package.

In the 'gulmake' package I listed the complete directory structure I used,
to make things as fool-proof as possible. Don't forget to start with the
'zoo' from Bammi's package first! Otherwise you need to be careful to
replace filename '_' with '-' unpacked from older 'zoo' programs.

A question comes to mind - the GNU 'tar' program seems to have extremely
small block sizes built into it, at least this is how I explain the
chain-saw-like buzzing off my hard disk while unpacking files. I've
never heard that sort of seek noise from any other program. Does

anyone know what's happening here? I haven't looked at the source.

> dgc

If you can give patches or end up having somebody selling (and
upgrading old versions, I hope 8-) please fix two more things.

1. Write the fats and directories asap (as you move the files) instead
of at the end of everything - PC defraggers do that and can be stopped
in the middle of things and lose nothing, or have a blackout and only
lose 1 file - which a utility can sometimes recover. The time saved
in doing it the old way (1st move all files, then write fats and then
directories) is not worth the agony IMHO (and is not so slow on the PCs

either, in my experience 8-).

2. Run a spell checker on the strings in your code 8-). I'm tired of reading that such and such a file is now "contigous" ("contiguous" is the correct spelling 8-).

Good luck, (for all of us, if you can swing distributing the fixes 8-).

Two answers:

Cheap:

There's a free or shareware mono font substituter - I have it but have forgotten the name. It had only 1 (pleasing) font to load in place of the standard one. It uses fonts with the .fed extension. Somebody update this info please.

Expensive:

Get the do it all desk accessory Harlekin (2 versions, one for med rez and one for high rez - get what you need). One of it's functions is to replace the regular fonts with other monospaced fonts. NeoDesk 3.0 also supplies a program to substitute monospaced fonts - but it has been critisized as slow in this forum.

1460. RL/RL HD help

Newsgroup: comp.sys.atari.st.tech
Date: 1991-02-22 00:37:07 UTC
From: arpajian@rodan.acs.syr.edu
Message-ID: <1991Feb22.003707.24205@rodan.acs.syr.edu>
Source record: 48999
Cross-posted to: comp.sys.dec,comp.sys.mac.hardware,comp.sys.atari.st.tech,comp.sys.pc.hardware,comp.sys.amiga.tech

I have recently been given a RL/RL drive and would like
to attempt to hook it up as a SCSI HD. The drive was manufactured by
Integrated Solutions; the actual drive mechanisms inside the enclosure
are IMI5012H (?). I also have the IS RL101 Winchester Disk Controller...
(for all the good that does me... I really DON'T want to hack an
LSI-11 to SCSI adapter cludge, and I think using a 11/73 as a
BIG microcontroller is a serious waste...) So here are my questions & pleas:

1: Are there any SCSI<->IMI5012H controllers available?

2: Can anyone tell me the pinouts for the above mentioned drives?
(A desciption of the handshaking & general protocol would be nice
also...)

3: Would I be stupid (and insane) to try and cludge a SCSI replacement for
the RL101 ?

4: Does anyone know the phone# and/or anddress of Integrated Solutions, INC.?

Well thanx for your time.... please email me (i'm posting this to a few
groups that I don't normally read)....

arpajian@rodan.syr.edu

p.s. -> yes I do realize that this is a hell of alot of work to go thru for
a 10M drive...

Hello everyone,

I recently came across a few 3d objects file for Atari CAD 3D
program while ftping. I search thru all archives of comp.graphics and found
a few articles in around '87 '88 that were discussing this file format. From
the articles, I was told that the numbers are stored in Motorola Fast Floating
Point Library format (LIBS). However, these articles didn't give enough
information to allow me to extract data from the data files. The data files
I have are in binary and there are the old CAD 3D format. Not the newer 3d2
format.
Can anyone please tell me how can extract data out, or how can I get
documentation on this format? ALso can anyone tell me what is the Motorola Fast
Floating Point Library Format? I have also search thru Compuserve's Atari
forum and still couldn't find any information.
I greatly appretiate any help. Thank you very much.

Here's the catch: You're *not* transferring text. You're transferring a formatted file that should be regarded as binary.

If you really want to transfer it, use a communications protocol such as Xmodem or Zmodem. But I suspect that's not really what you want to do. Of what use would a First Word-formatted file be on a Unix system?

You probably really want editable plain text. There are a couple of ways to get it. One is to load First Word, deselect WP mode (in one of the drop-down menus) and save the file as plain ASCII text. Another is to use a stand-alone conversion filter program; I've seen several over the years, but I don't know if any are currently in the archive.

This is a common problem, by the way. The general solution is to look for a way to ``print to disk,'' i.e., create a disk file that is plain text. Many word processors have such an option. In such cases you may have to tweak the formatting a bit. For example, ST-Writer can save ASCII by printing with 0 left margin, 0 top and bottom margins, and no page numbering.

Not long ago I helped a friend extract his brother's detective novel from Wang word processor format. Now, that was a chore! A fellow in Australia (praise the network) sent me a conversion program that rescued us. Without that program I suspect I'd still be wrestling with it.

OK, so it's possible to compile GCC/G++ on the ST if you have the time (:-)
But is it also possible to compile EMACS ?
And/Or has anyone made an attempt to get emacs running under mint, taking
advantage of this new environment ? If not, and if it is possible to compile it on my ST,
I'll have to do it myself I guess... I really hate that I can't press CTRL-G in emacs
(under MGR), and I also hate the cursor blinking on the desktop under MGR/emacs.

I will soon need to upgrade my old TOS 1.0 520STM to possibly 2.5Mb, it has already been upgraded to 1Mb using piggy-back chips by its previous owner. This is fine, but when I asked some companies if they would do the bigger upgrade they threw their hands up in horror and said that due to the piggy back mod., they could not possibly consider even taking the top off the machine !.

I would therefore like very much to know if anyone has discovered a company who WILL do the work, preferrably within the UK, or someone who can supply a good kit that I could fit myself.

Cross-posted to: comp.sys.atari.st.tech,comp.sys.atari.st

I'm sure this is not a new problem, but it's new to me and perhaps someone can help.

The mouse supplied with my Atari ST has started to play up. The problem's with the left-hand button, which more often than not doesn't respond. Pushing harder can make it work, but double clicking is just about impossible.

The microswitch itself works fine, as the mouse can be operated without its cover, and no problems occur. Also, the button mechanics in the top of the mouse look OK as far as I can tell.

This leads me to believe some misalignment has developed between the plastic bit you press, and the switch itself.

Does anyone have any experience of such a problem, and (I hope) know of a solution?

Email responses would be fine.

Thanks

Phil Lloyd

First, read the doc on Ptermres(). It tells you how to terminate a program
of yours aqnd stay resident. If you want something like a hot-key, you will
have to link your program into one or the other vector; in a screen saver,
for instance, you might intercept the mouse movement vector so that
a routine in your programs is being called whenever you move the mouse.
These are the basics how it works - details depend on the kind of TSR
you want to write.

1469. Monitor change

Newsgroup: comp.sys.atari.st.tech
Date: 1991-02-22 13:36:18 UTC
From: dodgson@sol.cs.wmich.edu
Message-ID: <1991Feb22.133618.14039@sol.cs.wmich.edu>
Source record: 49006

I have seen this subject appear here before, but I have seen programs
that change from monochrome to color totally and with no problems and I would
like to know how they do it. I have a STacy and when I run the Defender II
demo (which I just uploaded to atari.archive), it turns off the backlighting
and starts running as if I had a color monitor plugged in. When I plug in
the monitor, there it is running properly. The older games I have, just
either complain that I need a color monitor or reboot the machine with extreme
prejudice. I would like to get the code that does the switching and run it
before I run these games or incorporate it into my own programs when I need
to be in color mode.
Also of note is the way that the people who made 'Brataccus' coded
their routines such that you can plug in and unplug the monitors at any
time and it will display correctly on the current one. Too bad the controls
don't work with the STacy. I just run until I hit a wall when I try to play
it.
I also uploaded ST writer Elite ver 3.8 this morning. I got these
off from the FEB 1991 Atari ST USER magazine disk. Of curious note is that
the disk also contains ver 1.5 (!!!!) of QuickST with all the old docs
including old address and phone for Branch Always Software. Who says that
the European market gets all the good stuff first? :-) :-)

I don't have access to FTP from my node, but I was wondering if somebody could E-mail me a copy of the PD assembler called "Turbo Assembler"? It would be greatly appreciated.

huh, there is already a solution. if your compiler/shell does'nt
support the atari or mwc extended command line conventions, complain
bitterly to the author. as for the desktop/neo and other such junk,
you get what you get... (as you can tell, i really dislike brainless,
half baked, clickity clack interfaces like gem).

That's the ticket, thanks. Two other people gave me the info also,
and I thank you all.

I think I agree with someone who previously said that this net is
worth a million bucks! You people are really great!

I also would like to mention that I appreciate when I get multiple responses.
It really helps to solve the problem in case you don't understand what
to do even after getting the first reply. I'm going to remember this
in case I know an answer to a question and think 'someone else' will
get back to the person.

i guess others will be interested too, so i am posting instead of
mailing. the makefile defines DEFBLOCKING == 2, so things are done with
blocksize = 2 * 512. you can change this by using the 'b' (set
blocking factor) command line option, or by recompiling with a large
DEFBLOCKING.

>of at the end of everything - PC defraggers do that and can be stopped
>in the middle of things and lose nothing...

I suggested to Norton that they modify SD to write files temporarily into the HIGHEST numbered free cluster instead of the LOWEST numbered free cluster. The effect of stashing a file in the LOWEST numbered free cluster is that it gets moved over and over and over and over and over ... again. Stashing it in the HIGHEST numbered free cluster increases head motion, but reduces the probability it'll have to be moved again before being moved to its final resting place. Overall, it should make the de-fragger substantially faster.

I hope to see a de-fragger of the kind desired by Pegram, with the above modification to the algorithm.

Van.

We *have* thought about solutions. That's what the extended argument passing spec is for. It's pretty widely accepted, I think. It's the same as the MWC method, using ARGV= in the environment, except (A) there is no information about file handles (you can find out other ways), and (B) there is a special value in the "length" byte of the command line to tell you the environment's ARGV= is valid.

I will try to find the extended argument spec document and post it again.

1476. Standard SCSI id-s?

Newsgroup: comp.sys.atari.st.tech
Date: 1991-02-22 22:38:03 UTC
From: saj@chinet.chi.il.us
Message-ID: <1991Feb22.223803.15036@chinet.chi.il.us>
Source record: 49013

I'd be interested to see a listing of the default SCSI id-s of various common Atari ST items. How does the beginning go, hard disks are generally 0 and 1, a laser printer is generally 4....that sort of thing. Mostly so that those of us who occasionally do ignorant things to our setups for amusement will know a bit more about what we're getting into. What's a common id for tape drives? Network adaptors that use DMA? Whatever else?
Steve saj@chinet.chi.il.us

1477. Putting TOS 1.0 on disk

Newsgroup: comp.sys.atari.st.tech
Date: 1991-02-23 06:37:26 UTC
From: rlcollins@miavx1.acs.muohio.edu
Message-ID: <3943.27c5c756@miavx1.acs.muohio.edu>

Ok, this might have come up before, but I thought I would ask.

Since I upgraded to TOS 1.4, is it possible to put 1.0 on a disk, and make it so I can boot up with 1.0 if I need to? (I own both, so there wouldn't be anything illegal, would there?)

There are a few games that I would like to play, that I can't now that I've upgraded.

Thanks.......

1478. ATARI SM124 Monitor Problem: Please Help

Newsgroup: comp.sys.atari.st.tech
Date: 1991-02-23 15:10:19 UTC
From: smisra@eos.ncsu.edu
Message-ID: <1991Feb23.151019.12729@ncsu.edu>
Source record: 49014

I suddenly started getting problems with my well kept monochrome monitor...for some reason the monitor just turned off by itself...since the symptoms were very indicative of a blown fuse (that is absolutely no power anywhere) I opened up the case and replace the fuse... and then I turned it on...it work fine for about five minutes then the fuse blew again...I again opened up the case and replace the fuse (with the same voltage and amperage that the original one was) and then even sooner than the first one (about 2 minutes it was on) the fuse blew again. Does anyone know what is going on here?

Thanks
Saurabh

1479. SM124 Problem

Newsgroup: comp.sys.atari.st.tech
Date: 1991-02-23 20:32:49 UTC
From: PMR2@psuvm.psu.edu
Message-ID: <91054.153249PMR2@psuvm.psu.edu>
Source record: 49017

For a couple of months now my monochrome monitor has been behaving strangely: when I turn it on, there's an all-white background (larger than the regular ST screen) which doesn't hold still. This is with the computer OFF, ie. when the screen should be blank. When I turn on the computer, the screen appears "behind" this pattern, as though one were looking at it through a film, so that what should appear black (like letters) is very indistinct. Strangest of all, though, is the fact that the computer's display is shifted to the right, and the right half of the display is not clipped but rather wraps around and stretches back over the other half.

If I simply let the system sit for a while (^ 90 min.) the background pattern eventually goes away, but the screen wrapping persists. If I smack the thing a few times (sometimes more than a few), the wrapping goes away and I can _finally_ use my system. Because of this, I've gotten into the habit of leaving the monitor on or turning the contrast down when I'm not using the computer. However, occasionally even then the pattern and wrapping reappear.

Now: this is getting tiresome, and I'm not so sure smacking my monitor is very good for it. I'm also not sure that leaving it on all the time is good for it. What might be responsible for the problem, and what type of solution (eg. repair/replace) might I employ? My system is a little over 4 years old (bought Nov 1986). In the past I have sometimes had a problem with the background pattern in the wintertime (only then for some reason), but it always immediately yielded to smacking the monitor once or twice, and the wrapping problem never occurred. Now it seems this is more than just an idiosyncrasy.

From some of the other postings here (and from the warnings on the back of the monitor), I gather that opening one of these things up can be very dangerous, so please tell me whether there's anything I can do that does not involve this (and if there isn't, what I might tell the person I take it to for repair). Also, there seem to have been a number of complaints about SM124s recently. If replacement is the only option, a) where do I find a new SM124 (& for how much $) and b) are there other alternatives besides getting a new SM124? (I am a poor college student etc etc)

Any suggestions, please email to PMR2@PSUVM.PSU.EDU or post if you think they'll be useful to others. Thanks.

Paul Ricker (PMR2@PSUVM.PSU.EDU)

1480. gcc 1.39

Hello Bart!

I prefered UNITERM it's a VT100 and VT200 emulator. Also you can use it a graphics-terminal (I think it emulates a Tektronics one). It has all well known file transfer protocols execpt z-modem. It is very stable (i had never a crash or a real bug in the one and a half years i use it) and it is public domain. You can get it via anonymous ftp from atari.archive.umich.edu.

From: aikc@castle.ed.ac.uk
Message-ID: <8682@castle.ed.ac.uk>
Source record: 49021

I have received a number of request about Cantrip, about what it is, and where it can be got. Rather than answer them all individually, I'll post a short description here, and hope to post a copy to st.binaries within a few days. (Those that hate adventure games better hit the 'n' key now).

Cantrip is a multi-user adventure game. It is written in C and there are versions to run on various multi-user machines. It is a text based adventure system. Players can interact with their surrounding and other players. There are some monsters (NPCs) but they are pretty dumb at the moment. I ported the game to the ST, using the Midi ports to build a simple network. Eventually the whole thing will be put in the public domain, but not until its finished. Meantime an almost finished set of binaries will be released. As far as possible I've kept the software apart from the scenario, so that people can create there own new world without having to learn C. Cantrip has a simple command language which can be included in any text, such as room descriptions. The inital adventure is not very large but shows how the commands can be used to build up various puzzles and effects.
I'll post it as soon as I can.

One solution that I've seen is one that Steve La did - he took a
2-chip TOS1.4 and put that into his 6-ROM machine. Then with a clip here,
a switch there and trace there he put a 2-chip TOS1.2 (or was it 1.0?) in
and viola - a switchable 1.0 to 1.4 machine. However, he told me he would
post the docs on how to do this, but I haven't seen them anywhere. Steve,
if you are still reading the net, have you found the docs? If so, can you post
them, or if you did, where'd ya put them?

If you have an harddisk you can use the Quick TOS prg. It is a utility which boots the TOS.IMG file from your HD. Very fast. You need also the orig. TOS 1.0 disk version. It is probably available at your nearest atari dealer.
Quick TOS is in the atari/utilities dir. in the terminator ftp server.

BTW does somebody have a TOS relocation routine? I'm actualy working on some modif. on the TOS 1.6 and I've enougth of burning EPROMs all the time...

Ciao everybody --- Rick

hoho, you're in for some fun
you hve to do that on the inside. get some plastic tv adjustment
tools fromradio shark or someplace. open the monitor case and look down
onto the main board. they're all labeled pretty clearly (bunch of
little white potentiometers, and one adj. inductor, for which you will
need a plastic hex head tool).

I have also had this problem with my ST mouse....one way I fixed it ws to
take it apart a
and where the micro switch is glue a small piece of plastic from a model
on the switch or the rod coming out of the left mouse side. There might
also be a problem that the case isn't down tight enough on the mouse so
tighten up the screws first and see if it is snapped down before you glue
anything on to it..

Hope this helps

>Perhaps someone can answer these questions about Darek Mihocka's (Hope I got
>the spelling right...) 8-bit emulator Xformer?

John, I posted a long message to this topic a few weeks ago that will answer any other questions you may have about Xformer. Sorry I don't have a copy of it around, so if anyone has a copy, please forward it to John.
There are 3 versions of Xformer available: ST Xformer (for the ST and STE), TT Xformer (for the TT) and PC Xformer (for MS-DOS). The TT Xformer and PC Xformer have not been released yet. TT Xformer runs too slow for my liking, and PC Xformer is waiting for approval from Atari Corp since the original agreement was only valid for use on the ST.

> 1) What are the pinouts for the Xformer cable (to hook up the 8-bit's drive)?

The pinout and instructions are included in the Xformer manual. You can get a copy from me or from BRE software in California. (They have ads in magazines). Only supported in the ST version.

> 2) How does Xformer handle input from the joysticks? Are all 4 of the 8 bit's
> joysticks supported? Are only two? Do they plug into the ST's Mouse and
> joystick port? How about the "Paddles"?

2 joysticks, exactly like the 130XE and 800XL. No paddles. Not supported in the PC version.

> 3) How well does it do with disk based copy protected games? Does the
> "virtual floppy support" (files on hard disk) support disk based copy
> protection?

THe Xformer Cable will handle some, but not all, copy protected disks. Virtual floppy disks do not support copy protection unless you know of some way to transfer a copy protected disk over to the ST.

> 4) How fast is it compared to a normal 8-bit?

ST version: 40%-50% normal speed. TT version: 80%-90% normal speed.
PC version: 20%-500% (depending on the processor: 8088, 8086, 286, 386, 486).

> 5) Could someone post the source code for Xformer 2.55 to terminator (Darek
> said it's now PD and is on Genie, but I don't have an account there. Has
> it made it to Compu$erve, or anywhere else I can get it?

That source code is now old due to version 2.6. What do you really intend to do with it? I'm still waiting to hear back from the guy in Toronto who is porting it over to GFA Basic.

> 6) Has anyone tried M.U.L.E. or Seven Cities of Gold on it yet? If so, how
> did they work?

The copy protected versions do not work.

Pardon me, I'm the fellow with a TT and little Atari experience.

1) I'm still looking for a ramdisk that works on the TT. Atari sent me
one without instructions, "external 2" gives me two bombs.
No ftp access. Does anyone KNOW a TT-compatible one?

2) I need to switch from using the CON:sole text output to using the
VDI routines. How can I set the "background" color of the text (using
v_gtext to write text)? What VDI command(s) will replace the scrolling
action of the console? I couldn't find any "ScrollRaster" function.
And: how do I set the color of the screen that appears at the bottom when
you scroll up? It always wants to be black (0).

3) Are there any big problems in moving from MWC to Lattice (in case
anyone has done this already)?

Thanks, dear folks.

Ben@VersaSoft, makers of dBMan.

1494. PLCC Sockel

Newsgroup: comp.sys.atari.st.tech
Date: 1991-02-26 07:56:49 UTC
From: hades@uni-paderborn.de
Message-ID: <1991Feb26.075649.24770@uni-paderborn.de>
Source record: 49033
Cross-posted to: dnet.atari,comp.sys.atari.st.tech

Ich habe seit einiger Zeit immer wieder Probleme damit, dass mein 1040
aus heiterem Himmel abstuerzt. Angefangen hat die Geschichte wohl damit,
dass ich ihn auf 2.5 MB aufruesten liess -- ein Bekannter loetete
modifizierte Sockel auf die zweite RAM-Bank, die seither 16 Siemens
RAM-Bausteine mit 70ns Zugriffszeit enthaelt. Ein paar Monate spaeter
baute mir ein anderer Bekannter (ich selbst bin *kein* Hardware-Bastler)
Eproms ein, damit ich zwischen meiner alten Betriebssystemversion und
KAOS-TOS umschalten kann.

Nach dem letzten Umbau fing mein Rechner an, immer haeufiger auszufallen,
was schliesslich damit endete, dass er ueberhaupt nicht mehr lief. Auf
dem Transport nach dem Einbau der Eproms musste sich wohl Feuchtigkeit
in den Rechner geschlichen und dort ein paar Kontakte oxidiert haben.
Nach Reinigung der #%$@ PLCC-Sockel und der Bausteine darin -- ich
glaube, das sind MMU und GLUE -- bequemte sich der Rechner dazu, erneut
seine Arbeit zu verrichten. Die Freude waehrte jedoch nur kurz, und die
Frequenz der Reinigungsprozeduren stieg dramatisch an.

Als es soweit kam, dass der Rechner nur noch stundenweise durchhielt,
entschloss ich mich, noch ein paar Maerker fuer neue PLCC-Sockel zu
investieren. Nach einigem Warten besorgte mir der erste Bekannte zwei
Sockel, deren Beinchen dann erst noch in muehseliger Handarbeit auf das
Raster des Atari zurechtgebogen werden mussten.

Um zum Ende zu kommen: Seit drei Wochen habe ich die neuen PLCC-Sockel
jetzt drin. Der Rechner laeuft auch, stuerzt jedoch sporadisch -- mit
null bis n+1 Bomben -- ab. Die Ursache muss noch irgendwo in der Hardware
sitzen, da es voellig egal ist, welche Programme ich laufen lasse -- mit
einer Ausnahme: ein RAM-Testprogramm kann ich waehrend der Nacht laufen
lassen, ohne dass irgendein Fehler auftritt. Wenn ich aber meinen
bevorzugten TEMPUS-Editor starte oder auch nur mit FCOPY eine Diskette
formatiere, dann muss ich jederzeit mit einem Absturz rechnen.
Es ist dabei einerlei, was fuer Accessories oder residente Programme ich
lade oder auf welche TOS-Version ich umgeschaltet habe.

Nun ein paar Fragen:
- Hat jemand schon einmal etwas Aehnliches erlebt?
Falls ja, hat er das Problem zuverlaessig beheben koennen?
- Koennten diese Abstuerze evtl. durch anderweitige Bausteine meines
Rechners verursacht werden?
- Koennte es ein Waermeproblem sein? (Es ist allerdings egal, wie
lange der Rechner lief, er kann jederzeit abstuerzen.)
- Wuerden Klammern auf den Sockeln helfen?
Falls ja, kennt jemand eine gute Quelle fuer solche Klammern?

Jedweder Ratschlag ist willkommen. Ich moechte aber nicht die GLUE oder MMU nochmal aus den neuen Sockeln holen, wenn ich nicht sicher sein kann, dass das Problem dadurch wirklich behoben wird! Ausserdem moechte ich nicht mehr allzuviel Geld in diesen Rechner investieren. Eine neuer GLUE oder eine neue MMU kaemen also nicht mehr in Frage.

Freundliche Gruesse,
Hans-Detlef Siewert

++ I really hate that I can't press CTRL-G in emacs (under MGR),

This bit me for a while until I tracked it down --- it is a "feature" of 'vt52.prg'. ^G is defined as an abort character, which causes it to drop out the whole caboodle. Try recompiling vt52.c in your mgr sources, assigning a different character to the abort. I am successfully using 'me.tos' inside an mgr window with something like the following (ksh) function ...

```
function ved()
{
vt52 me.tos ${1}
echo '\014'
}
```

Question --- has anyone succeeded in getting mgr to recognise any of the ST cursor keys, or the HELP/UNDO keys?

I have another question. With a machete, I rejigged 'zmdm' to run under mgr (removing the screen memory calls and anything else I thought might interfere with mgr), and it works, but whilst it is connected to the RS232 port, mgr/mint/kshv4 (something, somewhere in that trio) prevents me both from opening other windows (can't get a pty) and from doing anything in another already-existing window (cannot fork, try later). Could anyone hazard a guess as to whether it's something I did to the zmdm code, or whether there's something else that's biting me.

I redid the whole thing as an mgr application, using mgr library calls, but I suspect that m_setup() remaps the ports 'cos I can't get any characters out of the rs232 port, I wonder if Bconstat(rs232) is actually checking the rs232 port? Bconstat(console) seems to work OK.

RE: Which MMU's can go to 4 megs.

From the ZRAM upgrade docs:
If your machine's MMU has a part number of: CO25912-38 it WILL handle
a memory upgrade. I don't remember the number of the bad MMU.

If you need a new one both B&C Computervisions and Best Electronics
(Both located in CA, I believe) have them in the $25-$35 range.
I bought one from B&C and it works.

I installed the Zubair Z-ram in my machine, and it works fine, even though I've also got a 1/2 meg piccyback upgrade, now disabled. But the Zubair MMU adapter overlaps the 68000 a little bit, so installing something like PC-SPEED or AT/SACK is impossible. I understand there's another upgrade, similar to Zubair's that doesn't suffer from the too-big-adapter-board disease.

The problem is zmdm is taking up all of memory. Use the 'limit' program distributed with MiNT and it should work OK. For example:

```
limit -m 512k zmdm.ttp
```

By the way, has anyone noticed that certain programs (such as the CPM emulator) completely ignore 'limit' and snarf all of memory anyway?

It's a bug. Mea culpa. Your solution (recompiling vt52.c) should work admirably.

> Question --- has anyone succeeded in getting mgr to recognise any of the ST
> cursor keys, or the HELP/UNDO keys?
>

Nope. The best you could do is write a program that uses Keytbl() to remap those keys to something else before running mgr. The reason is that mgr only passes the lower 8 bits of characters to applications, so HELP etc. all get mapped to ^@.

> I have another question. With a machete, I rejigged 'zmdm' to run under mgr

Sounds like something is grabbing all of memory. Does zmdm use Malloc(-1L) to allocate a buffer, by any chance? You could try using "limit" to restrict the amount of memory it will steal.

> I redid the whole thing as an mgr application, using mgr library calls, but I

>

No, Bconstat(rs232) should always talk to the rs232 port under MiNT. The console (BIOS device 2) is the only one that is ever re-mapped. It is true that m_setup() does a _binmode(1) call, so all stdio stuff is in binary mode. However, I can't zmdm using the stdio package for I/O! The only other thing I can think of is that zmdm might be getting some sort of job control signals from the terminal; if you want to be sure, you might

try opening "AUX:" and then using ioctl() to set the process group of
the rs232 port to the process group of zmdm.

Hello !!

It is a long time ago, since i tried to get some information
from ATARI Corp. and other companies about memory upgrade, cache
(MAXON promised one) and graphic expansion (ATARI talks about one)
Nothing happened then. So my question is: What about you ??
Do you know sources where I can get this Hardware from ??
I WANT 26MB INTERNAL RAM !! I WANT MY 16 OR 32KB CACHE !!!
I WANT BETTER GRAPHICS !! I WANT I WANT ... AND I WANT IT ON MY TT !!
Ok I know ther are UNIX - machines at the same cost (I have the TT
because of UNIX) but I`m an ATARI-fool so never mind !
Thanks for information .

Source record: 48893

Possibly someone out there has experience coaxing Atari ST compatible diskettes out of a SUNSparc station 1. I've installed MTOOLS, which supposedly does MSDOS compatible diskettes. I was under the impression that this format was very close to Atari`s. But beyond being able to read the directory and the first few bytes of any file, there doesn't seem to be much I can do with a disk made this way. I tried formatting on both the SUN and the Atari, and the disks work fine on the SUN. Same problem as above though when I put the disk into the ST.

Now, I had to reconfigure the kernel on my machine, hunt down manual entries galore and try every sneaky way to get the disks to work. Right now the only other step I can see is to either change the source to MTOOLS for full Atari compatibility, or to write a driver for the Atari that reads MSDOS and writes Atari. Any better ideas? Anybody know of tools like this that already exist?

To do this mod, you have to take the casing off the monitor. There are screwdriver adjustable
pots inside that are, for the most part labeled. You'd probably want a plastic-handled, well-insulated screwdriver for this (JUST IN CASE YOU LAY THE DAMN THING AGAINST SOMETHING NASTY!!!!!)

1509. Mouse problems in a deskacc

Newsgroup: comp.sys.atari.st.tech
Date: 1991-02-27 16:39:45 UTC
From: waal@cwi.nl
Message-ID: <3044@charon.cwi.nl>
Source record: 48896

Hi,

I have a problem with a deskacc that I have written, and I can't find any clue on what I am doing wrong here. I would appreciate any feedback on this.

The source of the main program loop is included at the end of this message.

The main part of the program is a dialog that is handled in the function do_main_dialog. It draws a dialog box on the screen and waits until a button is pressed. We need to consider only two buttons that can be selected: PLAY1 and INFO.

If PLAY1 is selected, the mouse is changed to the BusyBee (or Hourglass) form, switched on, and after some time (and some actions on the MIDI port) switched off again. Then the PLAY1 button is deselected and the main dialog starts all over again.

If INFO is selected, a new dialog box is drawn over a part of the main dialog box. Clicking the OK button in this info dialog (see the function do_info_dialog), deselects the OK button, removes the info dialog from the screen and returns to the main dialog.

The problem is: As long as I do not use the INFO dialog in the deskacc version everything works correctly. If I select the INFO button once, however, then the arrow does not change anymore into a BusyBee when selecting PLAY1. Instead the arrow disappears, and returns as an arrow after the MIDI actions are finished. In the Desktop PRG version, this problem does not occur.

I am using GCC 1.37 for compiling, but I do not expect that this is a compiler problem (since the PRG version works flawlessly). I also do not think that the problem is in redrawing the main dialog after an info dialog. If I force the main dialog not to redraw after an info dialog (changing the code in place "ref1" to redraw_needed=0), gives a lot a trash on the screen, but still the same disappearance of the mouse as in the original version.

Rather interesting comparison - so 486s eat 030s. Too bad about the
640K though 8-). I run up against it far too often at work, TGFU (thank
god for Un*x). Even my 2.5 Meg ST does better, w/o expensive third
party memory allocation libraries 8-). Now if only TOS and DOS could
get away from 8.3 file names.

1511. The format of Mac disks and Spectre disks

Newsgroup: comp.sys.atari.st.tech
Date: 1991-02-27 19:17:51 UTC
From: rlcollins@miavx1.acs.muohio.edu
Message-ID: <4014.27cbbf8f@miavx1.acs.muohio.edu>
Source record: 48898

Does anyone know where to find out the format for Spectre disks? And also the format of a real Mac disk? I've ask in comp.sys.mac.programmer for the specifications of a Mac disk, but have received not a single rpely or followup to my original post. I've checked the library at school and couldn't find anything either.

I downloaded the file specstuf.lzh from atari.archive. It has a program that can format a 720k MFM Mac disk on the Atari that you just stick into a Mac with a HDFD and it reads it no problem. (This is without any extra software one the Mac end.)

I would really like to figure out the different formats, so maybe I could write some sort of conversion prg that would convert from mac<->spectre<->ST.

Any help would be appreciated.

Actually, it's quite easy. As you said, the MS-DOS and Atari disk formats
are very close; all that differs, in fact, is the boot sector. All you have
to do is write an MS-DOS boot sector onto a standard ST disk (I use DC
Formatter 3.0 for this), and your disk should read and write okay on an
MS-DOS machine. Once you've done this, MTOOLS should be perfectly happy
with the disk. I've successfully transferred files between my ST and a Sparc
station like this several times.

Note, however, that disk must be formatted in standard format - 80 tracks, 9
sectors/track, and non-skewed (non-twisted).

>
>brad@bnr

I think I know what your problem is. Mtools works fine going from ST -> SUN
but I had problems going from SUN->ST. The directories were intact, and so
was the first sector or so of info for each file but that was all. I think
that the problem is that one of the flags needs to be set when you compile
Mtools for use withthe ST.

Try compiling the init.c code with the DUP_FLAG set; it has something to do
with rewriting FAT tables. I haven't had a chance to give it a shot, so
I don't know if it works for sure. (There was some discussion about this
a few months ago, I beleive. Apparently this doesn't bother PC's.)

OK, now that I have financial info on STacey, I need some technical info...

1.) Will the screen do all resolutions (if not, which ones)?
2.) Can the STacey be equipped with an internal modem (esp 2400bps) (VERY IMPORTANT!)
3.) Does the machine have any standard ports (printer, external disk, monitors, etc)
4.) In addition to the battery power supply, can it be plugged into a standard outlet?

5.) ANY THING ELSE????

1515. sickly 1040st nneds help!!

Newsgroup: comp.sys.atari.st.tech
Date: 1991-02-27 22:11:13 UTC
From: drp9500@isc.rit.edu
Message-ID: <1991Feb27.221113.3677@isc.rit.edu>
Source record: 48908
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

I have an Atari 1040st with a problem....

It seems that the damn thing wont boot ANYTHING from the floppy drive. The drive checks out fine (tried it on another machine), the controller chip is fine (replaced it). I just checked the power supply to see if THAT was the culprit, nope. Checked the power line into the drive just in case, hmmmmm I got 13 volts going to the drive instead of 12......I wonder....The drive is a Chinon model F-354 EAT (that's DSDD to the rest of us).

ROM chips (TOS 1.0) are fine. Boots off a hard drive just dandy.

If I try to boot from a floppy I get a low res screen, and then I open drive A and get 0 bytes in 0 sectors EVERY TIME!!! I get this even if there IS stuff on the disk. Autoboot disks, nope. Non-GEM disks, nope. If I do a show info...lock up.

HELP ME PLEASE.......I want my baby back

1518. Re: ST Roms

Newsgroup: comp.sys.atari.st.tech
Date: 1991-02-27 23:43:25 UTC
From: vsnyder@jato.jpl.nasa.gov
Message-ID: <1991Feb27.234325.3936@jato.jpl.nasa.gov>
Source record: 48903
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

I have been poking around in the ROM with a disassembler, and have noticed some things that lots of other folks have probably also noticed. But attention could only improve them.

1. It's obvious that part of it was written in C and part in assembler. The parts that were written in C would be greatly improved simply by compiling them with a compiler having a decent optimizer. I don't know what quality optimizers are in existing ST compilers. But MetaWare has High C and Professional Pascal on 680x0 platforms -- it shouldn't be too great a trick to transport them to the ST. Probably the only way this will happen, though, is if Atari approaches MetaWare (408/429-META). The things one finds especially unpleasant about the present rom code are the complete lack of global common sub-expression elimination, especially array element references, and other just plain silly things that are almost completely local, such as "LINK 0" instructions.

2. The parts that were written in assembler would also benefit from being assembled with a better assembler. For example, the AssemPro assembler can be told to put references into PC relative addressing mode. There're lots of places where instructions have 32 bit addresses, but PC relative would work equally well.

3. Some of the stuff in assembler would benefit from simple things that a human must nonetheless do: all I/O addresses above $ffff8000 can be absolute short, because the hardware sign extends, that is, $ffff8800 can be coded $8800. Lots of little subprograms start "MOVE SR,-(SP)" and end "MOVE (SP)+,SR; RTS". They could instead end "RTE" or "RTR". There are a few places where one finds "MOVE.W #0,-(SP); MOVE.W #$xxx,-(SP)". These could be replaced by "MOVE.L #$xxx0000,-(SP)".

4. This isn't on precisely the same subject, but it wouldn't hurt to vector more of the intra-BIOS and intra-XBIOS calls. For example, I'd like to hook to a task scheduler at the point where FLOPRD goes into it's wait loop (What good is a DMA if the first thing you do after starting it is ask "hey, are you done? hey, are you done? hey, are you done? hey, are you done? hey, are you done? hey, are you done? hey, are you done? ... up to $60000 times)? If the intra-BIOS calls and GEMDOS-BIOS calls were vectored, one could replace FLOPRD, and not need to replace RWABS as well. Also, patches would be easier, when the inevitable bugs are found.

Is it reasonable at least to hope that the next ROM will be compiled with better tools, even if none of the expensive human-engineering intensive things are done?

1519. Problem Monitor SM 124

Newsgroup: comp.sys.atari.st.tech
Date: 1991-02-28 03:30:34 UTC
From: smisra@eos.ncsu.edu
Message-ID: <1991Feb28.033034.9498@ncsu.edu>
Source record: 48905

I had recently posted a message about a problem
with a SM124 that kept blowing the fuses.
I got different opinions, but pretty obviously
they all pointed to the power supply

Some said it was one of the diodes on the vertical board
Question: What does the vertical board look like? and aprox
where is its location inside the case

Some said it was was a blown rectifier...either a diode or a
big capacitor open...
Question: Where are these parts located?

Also does anyone know of a supplier for parts for the SM124
It was manufactured by Goldstar in June 1985. As you can already
tell, I am trying to save on repair costs on a 6 year old monitor.

Thanks again,
Saurabh

1520. STe memory upgrade

Newsgroup: comp.sys.atari.st.tech
Date: 1991-02-28 07:37:12 UTC
From: pdel@ADS.COM
Message-ID: <{#?&1L*@ads.com>
Source record: 48906

I just picked up an STe and popped off the cover (voiding my warranty)
to check out whether I can upgrade to 4 meg like the dealer said without
any adapter.
The simms in there now look kinda funny, but that's only because I've
only seen Mac simms, I guess.
Can I just pop in some standard 1 meg simms like you can get from
Mac mail order places? I heard something about 120ns or better, is
that right?

Thanks for any help.

Peter D.

> emulator) completely ignore 'limit' and snarf all of memory anyway?
>
There are two different flags for limiting memory: -M and -m. One of
them (I forget which) limits the amount of memory the process can Malloc;
the other limits the total amount of memory the process can have.
Some programs never use Malloc or Mshrink; they just keep all the memory
they're given on startup -- for them, you have to use the latter flag.

1525. help with memory problems

Newsgroup: comp.sys.atari.st.tech
Date: 1991-02-28 18:38:42 UTC
From: dth@cs.brown.edu
Message-ID: <66678@brunix.UUCP>
Source record: 48912

I added 512K to my 520ST using the "piggyback" method. This worked
for a while until I notice problems with the added memory. It seems that one
of the memory chips likes to flip bits. I suspect that it is a refresh/
access speed problem. I am thinking of removing and replacing the problem
chip, but I have no idea how to identify it. The errors always occur at
a particular bit--I think it's bit 4 in a 16-bit word. Can someone post
a list of "what chip number goes with what bit"?

In the meantime, how do I disable the added memory from
software? I remember comming across a program that configures the ST
to use only the first 512K of RAM at bootup. Can someone point me to
a source, preferrably anonymous ftp?

I have some hints about adding memory using the piggyback
method. I had lots of problem getting the computer to boot from the
floppy disk until I added some buffers to the address and CAS/RAS lines.
Basically, I removed the resistors that are connected in series between
the address lines and the RAM chips and connected TTL buffers in between.
That fixed the boot problem, but I still have the "refresh" problem.

1526. Re: Adjusting the SM124

Newsgroup: comp.sys.atari.st.tech
Date: 1991-02-28 18:48:08 UTC
From: bergmann@az35.informatik.uni-stuttgart.de
Message-ID: <8751@ifi.informatik.uni-stuttgart.de>
Source record: 48913

To adjust the screen size of the SM124 you have to open the monitor (Note: The wire of the built-in loud-speaker is connected to the platine with a small socket which you've got to pull off to get the casing open).

Then you have to look for the points on the main board that are marked with "VSize" and "HSize" (Vertikal/Horizontal size). By using a (plastic) screwdriver, it is possible to readjust the screen size in both directions. This way I have enlarged the size of my monitor screen to a good extent. Finally you should adjust the focus (can't remember the name for it on the platine now, though) to get the picture sharp (this is always a compromise - either the edges are clear or the center) and eventually you should center the screen with HCenter (I think...).

It is all not that difficult, only you MUST BE *VERY* CAREFUL not to get a severe electric shock and end up as a little heap of ash on the carpet!!! There is high voltage in some places inside the boxing, and the fact that you have to switch the monitor on to adjust it doesn't make it easier!

The best way to do it is:
1. Switch it off and leave it for at least 30 minutes like this; also, pull off all wires;
2. Open the boxing and then connect it to the computer, THEN to the mains again;
3. Run something like a test screen with a rectangular pattern or a square that you can check the proportions;
4. Make your adjustments, then disconnect everything and WAIT for another 30 min. (the monitor contains conductors that keep a high voltage for a good while), then reassemble the whole lot again...

Good luck!!! (...and don't electrocute yourselves!!!)

>Peter D.
>
> Hi Peter,
Yes, you can use standard SIMM's either 1mx8's or 1mx9's. You
can use SIMM's as fast as 70ns or as slow as 120ns; but 80ns and 100ns will be
the easiest to find, and the best priced.
Remember not to remove the entire RF shield from the motherboard, just
the small RF shield covering the memory (between the power supply and the flopp
drive). Bye.....

I got a monitor with the image tilted. If you carefully loosen the screws
clamping the deflection yoke to the picture tube neck, and TWIST the yoke
(but kon't slide it along the neck), you can correct this problem too.

In any case, observe the kind of safety precautions Bergmann outlined.

Hi -
I saw the note about upgrading a 520 to 2.5Mb when it already has an extra .5Mb added.
Well... I am a friend of the guy who has the Atari shop in town, and I do the tricky business there. I have spent a few hours on 3-4 machines of that kind, to manually solder in 2 1Mx8 SIMMs in 520s with junk on top of the old chips. Put the CAS of those pigs to +5V, and then testing. No customer has come back with complaints. Just glue the SIMMs with silicon glue somewhere in the box.

I have seen a news snippet in the UK Atari ST user group magazine that speaks of TWO companies offering magic boxes that allow the plugging of PC keyboards into the ST

They are DIVERSE DATA PRODUCTS - Miami (305) 651 2393
and ZUBAIR INTERFACES LTD - Lakewood (213) 408 6715

These phone numbers may be of interest to anyone out there interested...

My Question is - Are either of these companies on INTERNET as i would like to find out such tacky details as how much <and> how much to send to Australia <and> do they take VISA or MASTERCARD.

Thanks for any pointers...

> By the way, has anyone noticed that certain programs (such as the CPM
> emulator) completely ignore 'limit' and snarf all of memory anyway?
There are two different flags for limiting memory: -M and -m. One of them (I forget which) limits the amount of memory the process can Malloc; the other limits the total amount of memory the process can have.
Some programs never use Malloc or Mshrink; they just keep all the memory they're given on startup -- for them, you have to use the latter flag.

Please, Eric, give me some credit (I do know how to RTFM if nothing else). I've tried both flags independently and in conjunction and neither has any effect on the CP/M emulator.

I could swear I noticed another program that acted similarly but I can't for the life of me think of what it was right now.

In any case, I seriously doubt this indicates a problem with limit. It's probably just that the emulator does something really stupid (and likely illegal) to allocate its memory.

If anyone's had any better luck getting the emulator to use less memory, please let me know.

Source record: 48939

You have to open the monitor. I've found an article in an old STmag which discribes how to dow it: Get some plastic screwdrivers (metal would cause some induction). On the main board you'll find some potentiometers and one adjustable inductor (plastic drivers) . They have numbers on it, and i'll give you a short explanation:

VR 602 (V.Size) for the total height

L 702 (H.Size) for the total horizontal size

VR 603 (V.Line) for vertical picture distortion
(trigger only, when objects on the edge of the screen
(upper/lower edge) aren't ok, but in the middle)
L 703 (H.Line) for horizontal picture distortion

VR 601 (V.Hold) for a 'standing' picture
changing this poti will cause the picture to run from
upper to lower edge

VR 701 (H.Center) to center the picture horizontally on the screen

VR 703 (Focus) ATTENTION! High Voltage (600V) this is for the sharpness
of the picture

VR 702 (Sub Bright) this is the default value for the brightness, don't change
it.

Last some hints:
mark the initial value with a marker
notice every steps you're doing

Have fun!
Gregor

++ It's a bug. Mea culpa. Your solution (recompiling vt52.c) should work
++ admirably.

It does.

>> [HELP/UNDO seen by mgr?]

++ Nope. The best you could do is write a program that uses Keytbl() to remap
++ those keys to something else before running mgr. The reason is that mgr only
++ passes the lower 8 bits of characters to applications, so HELP etc. all get
++ mapped to ^@.

Ah, lux fiat. So, Keytbl() mapping of cursor keys to appropriate
control sequences would probably allow cursor key driving of me.tos
--- where's that compiler?

> [process problem with zmdm & rs232 port query]

++ Sounds like something is grabbing all of memory.

It was. Limit constrains zmdm to behave.

++ Bconstat(rs232) should always talk to the rs232 port under MiNT.

It does. Once I could actually get in to it, the core zmdm
read-rs232/console-echo loop seems to work OK.

*However* --- the poster who commented that the rz/sz code was "tight" was
quite correct, although I managed to hack zmdm around to work under mgr,
neither rz nor sz appear to work inside zmdm. C'est la vie.

Thanks for the info.

Does anyone own/know anything about the Hewlett Packard Deskjet
printer. I'm particularly interested in knowing how it performs
on an ST.
Are drivers easily available for it?
Is there a substitute driver that can be used from most packages with
it?
What is it's quality really like?
How expensive are the cartridges and - most importantly- how often do
they have to be replaced?

THanks in advance.

B.

No offence intended -- lots of people (myself included) sometimes overlook things in the FM even when they read it. I'm puzzled that the CP/M emulator ignores limit; does it otherwise work OK under MiNT (i.e. can you run it in the background and not have it interfering with other programs)? It's quite possible that, as you suggest, it simply uses all of memory without going through the OS; but in that case it probably will trash any other programs running at the time. Alternatively, there very well could be a bug in MiNT. (heaven forbid :-).

1540. My HD is slow to unpark. What to do?

Newsgroup: comp.sys.atari.st.tech
Date: 1991-03-02 00:54:28 UTC
From: johns@maccs.dcss.mcmaster.ca
Message-ID: <27CEF7C5.10738@maccs.dcss.mcmaster.ca>
Source record: 48927

I bought a used 65Meg Tulin HD. It's a great drive, and I like
it. Recently though, it's been giving me a bit of trouble.

It is self-parking, but when I power it up it doesn't seem to want
to unpark. I can hear it turn up to speed, then it just sits there.
Sometimes it will unpark and the computer will boot after 5, maybe 10
or even 30 minutes. Last night, it wouldn't come up, even after a few
hours, so I left it, and this morning it still hadn't unparked. Finally
at about noon I heard the happy sound of the head moving and the computer
finally booted. It seems that the delay is getting longer and longer.

Is there something I can do? Is it slowly deteriorating, and one
day it will just stop working altogether? What's going on?

I have a program called coldstrt.prg, a couple hundred bytes. I
put that in the auto folder on a disk in drive A, and then I just let it
sit there and try to boot. Except for wear on the disk, this shouldn't be
a problem, should it?

The Tulin is just a ICD host adapter and a Seagate mechanism. I
think the ICD software is version 3.01.

Thanks for any help.

>[...] Mtools works fine going from ST -> SUN but I had problems going from
>SUN->ST.

SUN->PC will also work fine. The problem with the earlier versions of mtools was that by default, it only wrote one copy of the FAT, and Ataris depend on the second copy. IBMs work OK with only the one FAT for some reason.

>Try compiling the init.c code with the DUP_FLAG set; it has something to do
>with rewriting FAT tables. I haven't had a chance to give it a shot, so
>I don't know if it works for sure.

I had the problem, and this is indeed the fix, except the flag is DUP_FAT. As someone else pointed out, a later MTOOLS version fixed this problem, but I have had trouble with our site's installation of it, so I still use my own copy (which *I* support :-).

Caveats: like IBM formatted disks, there won't be a random serial number on the disk, so you need to exercise caution putting them in: either keep them write-protected in the Atari or swap another disk in and out between any two of them. Also remember that you can only use double-sided regular density (720K) floppy format), not single-sided (360K) nor high density (1.44M) formats.

I posted a response to someone else's question about drivers for the HP Deskjet 500 a couple of days ago. You might look for that posting; if you can't find it, send me mail and I'll send it to you directly.

The quality is, in a word, excellent. A lot of the quality depends on the type of paper you use with it; if you use high-quality photocopy bond or a high-cotton bond, it looks really nice, almost like a laser.

The ink cartridges are $15 - $18 (U.S. dollars). I don't really know what their actual life is since I'm still on my first one. I imagine it'll print somewhere between 600 and 800 pages, but it really depends on how black the pages are that you print.

Feel free to send me mail directly if you have more questions.

I had the same problem about two years ago (caused by too much Dungeon
Master play I think) but my mouse was revived and is working perfectly
to this day.

Simply spray a VERY small amount of WD-40 on the top of the offending
micro-switch. Problem solved! {I have done this twice (once on my mouse
and once on a friend's which had developed the same problem). WD-40 is
an Australian product, but if you can find some stuff with a long, thin
applicator tube and advertising to the effect of "Starts Wet Motors,
Loosens Rusted Parts, Lubricates - Protects, Stops Squeaks" that might
be the equivalent in your country.

Hope that helps.

Has anyone attempted to use the IMG Scanner with the HP DeskJet printer? I am considering buying a friends. He graduated to a hand scanner. Will I meet up with incompatibilities by merging the IMG Scan with this particular printer??

I know this has been put on the net before, but what kind of mouse can be connected to the ST? (Don't tell me ST mice!-) I have a friend with what I think is a bus mouse (it seems to have a roundish connector?). Do I want a serial or bus mouse? And where do I get the info to hook it up?

Thanks in advance,

Dom Alvear

P.S. E-mail preferred as this is an old subject.

1547. Using g++

Newsgroup: comp.sys.atari.st.tech

From: rdf@pinet.aip.org
Message-ID: <1991Mar3.145701.16673@pinet.aip.org>
Source record: 48933

I'm trying to use g++. I downloaded the four g++.zoo files from terminator and put the files in the appropriate spots. I can't see any included documentation. When I say g++ file.cc everything seems to run by I get an out of virtual memory message after several minutes of computing. Where are the general or Atari specific docs on using this package. Do I need gcc or can I use my present compiler (Laser C) or does the g++ package make executables directly.

I am using a 1040st with 2.5megs and Gulam as the shell. Thanks...

1548. Repost: GEMDOS EXTENDED ARGUMENT (ARGV) SPECIFICATION

Newsgroup: comp.sys.atari.st.tech
Date: 1991-03-03 19:06:52 UTC
From: es2a+@andrew.cmu.edu
Message-ID: <YboIZAq00WB603ZZ89@andrew.cmu.edu>
Source record: 48934

I found a copy lying around, and thought I'd save others from digging to find it. I don't have the original attributions anymore, but I think it'd be safe to assume that it's Copyright Atari Corp...

------------cut here--------------
GEMDOS EXTENDED ARGUMENT (ARGV) SPECIFICATION

Introduction

The Pexec() function of GEMDOS allows a program to pass to a child process a command line up to 125 characters long, with arguments separated by spaces. No provision is made in GEMDOS for the child to know its own name. This makes it difficult for C programs to correctly fill in argv[0], the standard place where a C program finds the command which invoked it. Because the command line arguments are separated by spaces, it is difficult to pass an argument with an embedded space. This document will specify a method of passing arguments which allows arbitrary argument length, embedded spaces, and support for argv[0].

Standard Argument Passing

The Pexec Cookbook specifies how to use Pexec() to launch a child process, passing a command tail (argument string) and an environment. Before getting into the extended argument scheme, let's review how arguments are normally passed to a child.

A parent process builds a command line into an argument string - a null terminated string whose first byte contains the length of the rest of the string - and its address is passed as one of the arguments to Pexec(). GEMDOS copies this argument string to the basepage which it creates for the child. Thus the parent is responsible for gathering all the child's arguments into one string. This is normally handled by a library exec() function. The child is responsible for parsing the string of space-separated arguments back into an array of strings. This parsing is normally handled by the child's startup code.

Evolution

Several methods of bypassing the limits imposed by Pexec() have been used by GEMDOS programs. Some allow a user to specify a file on the command line which contains the rest of the arguments. Others get a pointer to the arguments, or the arguments themselves, from the environment string. Most MS-DOS programs use a command file for the extra arguments. This can be inconvenient for a user, cluttering the file system with command files, and making the operation of batch files and makefiles more confusing.

Several "standards" have arisen on the ST which use the environment to pass arguments. While more convenient than command files, these standards have other problems. Some rely on sharing memory between parent and child processes. Some take advantage of undocumented features of the operating system to get argv[0]. Others give the child process no way to validate that the arguments it finds are intended for it.

Rationale

In order to pass more than the standard 125 characters worth of arguments to a child, or to let the child find its name, the parent must place the extra information in a place where the child can access it safely and legally. The most convenient place is in the child's environment string. An environment string is a series of null-terminated strings of the format "VARIABLE=value" (e.g. PATH=c:\bin,c:\etc, or ShellP=YES). The last null-terminated string in the environment is followed by a zero byte, thus two consecutive nulls indicates the end of the environment. The environment is allocated for the child by GEMDOS, it is owned by the child, and its contents can be specified by the parent.

The child must have some way of knowing that the arguments which it finds in its environment are intended for it. The child may have been invoked by a parent which does not conform to this specification. Such a parent would leave _its_ arguments in the environment, and could pass that environment on to the child. The child would mistakenly interpret its parent's arguments as its own.

Placing arguments in the environment passed to the child gets around all of the command line limits of the standard Pexec() command tail. Because there is no limit on the length of the environment, arbitrary length arguments are supported. Arguments placed in the environment are null terminated, so they may contain spaces. A parent can also place the name of the command with which it invokes the child in the child's environment, providing support for argv[0]. Validation of the extended arguments can be placed in the standard Pexec() command line, by assigning a special meaning to an invalid length byte.

The GEMDOS Extended Argument Specification

This specification uses the convention that the presence of an environment variable named ARGV (all upper case) indicates that extended arguments are being passed to the child in its environment. This means that ARGV is a "boolean" environment variable. For the purpose of this specification, its value is not significant, but its presence indicates that the strings following it are the arguments for the child. Implementations of this specification are free to give the ARGV environment variable any value. The ARGV environment variable must be the last one in the environment passed to the child, so that the child can truncate its environment at that point, and treat everything before the ARGV as environment, and everything after it as arguments.

The first argument to the child (argv[0]) is the first string in the environment after the ARGV variable. This argument is the "pathname" parameter passed by the parent to Pexec(). The remaining arguments are those that the child would normally find in the command tail in its basepage. Even if all of the arguments would normally fit in a child's command tail, the parent should set up the arguments in the environment to take advantage of the benefits of this extended argument scheme.

As many arguments as will fit in the command tail will be passed there as well as in the environment, to support non-conforming programs. As a flag that arguments are also in the environment, the length byte of the command tail will be 127 (hex 7f). Non-conforming programs should not have a problem with this length byte, because it is longer than the maximum 125 bytes allowed by Pexec().

As an aside, the Pexec Cookbook erroneously implies that a command line can be 126 or 127 characters long. In fact, GEMDOS only copies to the child's basepage up to 125 bytes, or until it encounters a null, from the argument string passed to Pexec(). It ignores the length byte, placing a null at the same place it found one or at the 126th byte if no null is found. This has several implications: the length byte is not validated by GEMDOS (necessitating validation in the child's startup code, but also making this extended argument spec possible), and the null terminator _can_ be located after the end of the real command tail (the Desktop places a CR character after the command tail and before the null). The ARGSTART.S startup code listing below demonstrates how to correctly validate and parse a GEMDOS command tail.

A child which finds an ARGV environment variable can use the command tail length byte value of 127 to validate that the arguments following the variable are valid, and not just left over from a non-conforming parent which left its own ARGV arguments in the environment.

Because the strings in the environment following an ARGV variable are not environment variables, a child should truncate its own environment at the ARGV variable by changing the 'A' to a null.

Implementation: Parental Responsibilities

To pass arguments in the environment, a parent must create an environment string for the child. This can be achieved by first allocating as much space as is used in the parent's own environment, plus enough room for the ARGV variable and the arguments to the child, and then copying the parent's environment to the newly allocated area. Next, the ARGV variable must be appended, since it must be the last variable in the child's environment string. Following the ARGV variable is the null-terminated pathname of the child as passed to Pexec(), then the null-terminated arguments to the child, followed by a final null byte indicating the end of the environment.

After setting up the arguments in the environment, the parent must place as many arguments as it can fit in the command tail it passes to Pexec(). This way, a child which does not conform to this

specification can still get arguments from the command tail in its basepage. When placing arguments in the environment, the parent must set the first (length) byte of the command tail to 127 (hex 7f), validating the arguments in the environment.

Here is an example execv() library routine in C. It uses three local utility routines, e_strlen(), e_strcpy(), and str0cpy() for getting environment size and copying strings into the environment created for the child.

```
/* EXECV.C - example execv() library routine
* ================================================================
* 890910 kbad
*/

long Malloc( long nbytes );
long Pexec( short mode, char *filename, char *tail, char *env );
long Mfree( void *address );

/* Return the total length of the characters and null terminators in
* an array of strings.
* `strings' is an array of pointers to strings, with a null pointer
* as the last element.
*/
static long
e_strlen( char *strings[] )
{
char *pstring;
long length = 0;

while( *strings != 0 ) { /* Until reaching null pointer, */
pstring = *strings++; /* get a string pointer, */
do { /* find the length of this string, */
++length; /* using do-while to count the */
} while( *pstring++ != 0 ); /* null terminator. */
}
return length; /* Return total length of all strings */
}

/* Copy a string, including the null terminator, and return a pointer
* to the end of the destination string.
*/
static char *
str0cpy( char *dest, char *source )
{
do { /* use do-while to include null terminator */
*dest++ = *source;
} while( *source++ != 0 );
return dest;
}
```

```
/* Copy an array of strings into an environment string, and return a pointer
* to the end of the environment string.
* `strings' is an array of pointers to strings with a null pointer
* as the last element.
* `envstring' points to the environment string.
*/
static char *
e_strcpy( char *envstring, char *strings[] )
{
while( *strings != 0 ) {
envstring = str0cpy( envstring, *strings );
++strings;
}
return envstring; /* Return end of environment string */
}

/* Run a program, passing it arguments according to the
* GEMDOS Extended Argument Spec.
*
* `childname' is the relative path\filename of the child to execute.
* `args' is an array of pointers to strings to be used as arguments
* to the child. The last array element must be a null pointer.
* `environ' is a global array of pointers to strings
* which make up the caller's environment.
*/
long
execv( char *childname, char *args[] )
{
long envsize, ret;
char *parg, *penvargs, *childenv, *pchildenv;
short lentail;
char argch, tail[128], *ptail;
static char argvar[] = "ARGV=";
extern char *environ[];

/*
* Find out how much memory we'll need for the child's environment
*/
envsize = e_strlen( environ ); /* length of environment */
envsize += e_strlen( args ); /* plus command tail args */
/* plus length of argv[0] */
parg = childname;
do { /* use do-while to include null terminator */
++envsize;
} while( *parg++ != 0 );
/* plus length of ARGV environment variable and final null */
envsize += 7;
envsize += envsize & 1; /* even # of bytes */
/*
* Allocate and fill in the child's environment
*/
ret = Malloc( envsize );
```

```
if( ret < 0 )
return ret; /* Malloc error */
childenv = (char *)ret;
pchildenv = e_strcpy( childenv, environ ); /* copy caller environment */
pchildenv = str0cpy( pchildenv, argvar ); /* append ARGV variable */
pchildenv = str0cpy( pchildenv, childname ); /* append argv[0] */
penvargs = pchildenv; /* save start of args */
pchildenv = e_strcpy( pchildenv, args ); /* append args */
*pchildenv = 0; /* terminate environment */
/* put as much in the command tail as will fit */
lentail = 0;
ptail = &tail[1];
while( (lentail < 126) && (penvargs < pchildenv) ) {
argch = *penvargs++;
if( argch == 0 ) {
*ptail++ = ' ';
} else {
*ptail++ = argch;
}
}
/* terminate command tail and validate ARGV */
*ptail = 0;
tail[0] = 127;
/*
* Execute child, returning the return code from Pexec()
*/
ret = Pexec( 0, childname, tail, childenv );
Mfree( childenv );
return ret;
}
/* End of execv() example code */
```

Implementation: Prenatal Responsibilities

A program's startup code must handle getting extended arguments out of the environment. The startup code should get the basepage pointer off the stack, then get the environment pointer from the basepage, and search the environment for "ARGV=". If "ARGV=" is found, the command line length byte in the basepage is checked. If the command line length byte is 127, then the arguments in the environment are valid. The first argument begins after the first null following the "ARGV=". It is important not to assume that the null follows immediately after the "ARGV=", because some implementations may assign a value to the ARGV environment variable. After setting up an array of pointers to the arguments, the startup code should set the 'A' of the "ARGV" variable to null, thus separating the environment from the argument strings (remember: a double null terminates the environment).

Here is some example C startup code which shows how a child could look for arguments in its environment:

```
* ARGSTART.S - example C startup code
* using GEMDOS Extended Argument Specification
* ================================================================
* 890910 kbad

.globl _main ; external, C entry point
.globl _argv0 ; external, name used for argv[0] if no ARGV

sub.l a5,a1 ; size to keep
move.l a1,-(sp)
move.l a5,-(sp) ; base of block to shrink
pea $4a0000 ; Mshrink fn code + junk word of 0
trap #1
lea 12(sp),sp ; pop args
```

```
*
* Everything beyond here depends on implementation.
* At this point, _environ points to envp[], _argvecs points to argv[],
* and _stklimit points to the end of the argv array. Thus argc can
* be calculated as ((_stklimit-_argvecs)/4)-1.
* _main could be invoked as follows:
*
move.l a5,-(sp) ; basepage
move.l _environ,-(sp) ; envp[]
move.l _argvecs,-(sp) ; argv[]
move.l _stklimit,d0 ; 4 bytes past end of argv[]
sub.l (sp),d0 ; (argc+1) * sizeof( char * )
asr.l #2,d0 ; argc+1
subq #1,d0 ; argc
move d0,-(sp)
jsr _main ; call mainline
lea 14(sp),sp ; pop args
```

A Final Note

This specification was formulated with careful deliberation, and with input from several companies and developers who have created development tools for GEMDOS. The Mark Williams extended argument passing scheme was the main influence for this specification, because it has been in use, and supported by Mark Williams and other companies for several years. This specification is very similar to the Mark Williams scheme, with the following important exceptions:

1) Under the specification, the arguments after the ARGV environment variable may be validated by checking the command tail length byte. The Mark Williams execve() library function uses the command tail length byte as a telltale, but it is not checked by the crts0 startup code. This validation is important for the reasons mentioned in the Rationale section above.

2) The specification allows the ARGV environment variable to take on any value. Mark Williams uses the value of ARGV as an iovector, which is described in the Mark Williams documentation. The iovector should no longer be needed, as its primary purpose was to simplify the MWC implementation of the C library function isatty().

3) Some versions of the MWC startup code do not require the ARGV= to have an `='. Because ARGV is an actual environment variable in the specification, the equals character is required.

1549. Can VDI draw on a virtual screen?

Newsgroup: comp.sys.atari.st.tech
Date: 1991-03-03 23:37:57 UTC
From: micro@imada.dk
Message-ID: <1991Mar3.233757.10358@imada.dk>
Source record: 48935

Hi,

Is it possible to use VDI operations to draw on a virtual screen? Possibly
on a screen which is bigger than the real screen.

Now, I am drawing in a window, copying the inner to a buffer, and copying
it back into the window when I get a redraw, or determining which part
of the buffer is valid when I get a scroll or size, and then copy the
valid part into the window, drawing the other area(s), and then copying
the new contents to the buffer...
- It would be easier to draw in a big buffer, and only copy the portion
which is visible to the window.

I think that AIM is using a virtual buffer to it's images, but I guess
that it is using custom drawing functions...

-Klaus

>I had the problem, and this is indeed the fix, except the flag is DUP_FAT.
>As someone else pointed out, a later MTOOLS version fixed this problem,
>but I have had trouble with our site's installation of it, so I still use
>my own copy (which *I* support :-).

I ftp'ed MTOOLS 2.0.3 (originally trying 129.229.1.101, which gave me truncated files three times, so I think the files there are messed -- I eventually got them from 129.217.64.63 where they were in comp/msdos/mtools). The patches that were in the directory seem to be unecessary, as they are already applied to the sources there. Anyways, I think the only thing I did was add "#define SPARC 1" to devices.c (this would change if you were on a different machine) and compiled. The disks I used were Atari ST formatted with a MSDOS boot sector written over with DCFormat 3.0 (this program will also do an 2-9-80 normal (ie non-skewed) format on the disk before laying out the MSDOS boot block. Formatting from the SUN may be possible, but since this other format works, I haven't bothered.

>Caveats: like IBM formatted disks, there won't be a random serial number
>on the disk, so you need to exercise caution putting them in: either keep
>them write-protected in the Atari or swap another disk in and out between
>any two of them. Also remember that you can only use double-sided regular
>density (720K) floppy format), not single-sided (360K) nor high density
>(1.44M) formats.

The program 'uneekit.zoo' on atari.archive.umich.edu in /atari/diskutils/ is supposed to write a random serial on the disk. Haven't tried it yet, but now that I'm doing Atari<->SUN swaps I suppose I'll run it over some disks.

The only other SUN caveat I might add is that if you are not using the floppy presently you made need to fire up the 'fd' driver. I know I had to do that on this SUN I'm on, even though the floppy drive had been installed some months before I started using the machine (I guess everyone else thought it was a quaint aesthetic feature of a SUN Sparc, and not actually meant for use).

>Doug Monk (bro@rice.edu)
>
>Disclaimer: These views are mine, not necessarily my organization's.

Anyways, my thanks to those that helped me with this question. I brought home two disks with the Sozobon compiler and some utilities this weekend. Without

this I was faced with (ack, arrrrrgh) hours long kermit transfers from our local mainframe.

I also want to throw away the 512 KB memory in the 2nd bank of my 1040STFM and put in 2MB memory using 1M bit chips into it. Could someone please re-post or better e-mail me directly the detailed instructions to do the job?

I have a pretty old STFM (forgot the revision no.) with 1.0 TOS. The memory banks are under the keyboard and the CPU chip is near the diskdrive.

Thanks for the advise adjusting the monitor; I got to work.

I've noticed that one person has mentioned something about a inductor. When
I opened up the monitor, I only found the following adjustments:

V-line
V-Size
V-Hold
H-Cent
& one more having to do with the screen (I can't recall it right now)

I did not see the inductor adjustment. If it is supposed to exist, then
where is it? What happens if it isn't adjusted when one adjusts the screen
controls.

Offers a good explanation of the adjustments on the mono monitor, including:
> VR 701 (H.Center) to center the picture horizontally on the screen

Don't forget the mechanical centering rings on the yoke. They are metal rings with tabs on them. They should be adjusted for centering before the electrical adjustments are done. Remember the yoke has high voltage on it too (not thousands, but hundreds). These must be experimented with, since they don't simply adjust "up-down" or "left-right". They adjust "all-around", and must both be played with together to get the right effect.

1554. Blitter direct?

Newsgroup: comp.sys.atari.st.tech
Date: 1991-03-04 21:32:00 UTC
From: erik@mcrware.UUCP
Message-ID: <5187@mcrware.UUCP>
Source record: 48944

Can I access the blitter directly for moving video data quickly?

I am currently working on an animation viewer that does its work during the VBI. Right now copying an image to the screen using movem's takes approx 160,000 cycles or 1/50 sec (8Mhz), which is a little to much data to handle in under 1/60 of a second. I would like to make a version of my viewer blitter-ready (make use of it, if it exists).

Can I use the blitter directly to move the data in less time?

Is it safe to even use the blitter during a vbi?

Does the blitter access memory on video or cpu access times (that is, can both the blitter and cpu write to memory at 8 Mhz each (interleaved)?

And lastly, how do I detect the presence of the blitter?

If you could help me with any/all of my questions, it would be greatly appreciated.

Erik R Johnson

1555. *.ICN format of RCS

Newsgroup: comp.sys.atari.st.tech

Message-ID: <1991Mar5.004314.22107@ux1.cso.uiuc.edu>
Source record: 48945

Does anybody out there know what the format is for the *.ICN files that the Resource Construction Sets use? I am trying to write a little editor to be able to make my own icons, but can't seem to find any information on this. I do know the format of the iconblk, but this isn't what the RCS is looking for. Hmmmm.

Thanks,
Michael Stepniczka

1556. Porting GNU fileutils to MiNT

Newsgroup: comp.sys.atari.st.tech
Date: 1991-03-05 07:12:11 UTC
From: entropy@ai.mit.edu
Message-ID: <ENTROPY.91Mar4231211@wookumz.ai.mit.edu>
Source record: 48946

I've put a few hours work into porting some of the GNU fileutils to MiNT. So far I've got a (more-or-less) working cat, chmod, cp, cut, dir, du, head, ls, mkdir, mv, rm, rmdir, tail, and vdir. I've also got compiled cmp, dd, ginstall, and paste but I haven't tried them yet (I don't even know what they're for...)

Compiling them was easy except GCC kept crashing (Bus error or illegal instruction, both GCC 1.37 and 1.39) and there seems to be a typo in <types.h> (in struct utimbuf, axtime instead of actime, but I'm not sure if that was on purpose or what since I don't know what's supposed to be there...anyone know?) The rest of the utilities will require more work to port than I have time for right now. If anyone wants to pick this up from here I'll send you what I've got so far. I'll probably post them when I've cleaned them up a bit but if anyone wants them now to work on them, just let me know...

Eric and Jwahar, thanks for all your effort which made this sort of thing possible (are you guys getting sick of me thanking you yet?)

1557. Problems with Spectre GCR 3.0 reading floppy disks.

Newsgroup: comp.sys.atari.st.tech
Date: 1991-03-05 07:29:56 UTC
From: kron@netcom.COM
Message-ID: <26915@netcom.COM>
Source record: 48948

I am having trouble accessing store bought disks, disks created by other macs and even disks formatted by GCR. I just get disk errors when I try to copy stuff or sometimes the disk isn't even recognized as a MAC disk. These same disks are subsequently readable by other machines (real MAC's) and copies of the disks sometimes turn out more readable than the originals. This makes me suspect alignment problems but they don't show up in atari mode. Also I sometimes get errors when I format a disk in MAC mode and subsequently try to use it but when I run GCR test on these disks everything passes.

I've tried running the GCR test several times and it passes using the disks that I previously had errors on.
Anyone else have a simular problem?

BTW- I have no problems accessing files in ATARI mode.

> |||| Power Without How DO you move/copy a rc1dsanu@miamiu.BITNET
> / || \ The Price!! Subdirectory? R.COLLINS1 on GEnie
>--

I have written a little program to convert MAC 720k <-> Spectre 800k disks. The program can also format and initialize both formats (initialize is much quicker because you only need to write the first few sectors on an already formatted disk). But I would wait or use Spectre 3.0 with Danya's DOS Mounter to transfer data or programs from/to MAC/Spectre. the problem is that the MAC cannot read 800kB MFM-disks. i can upload the program if you like.

The main difference between MAC 720kB and Spectre 800kB is that Spectre first writes Side 1, then Side 2 while MAC writes every sector on both sides, eg.:

Spectre:

```
0| 1| 2| 3| 4| 5| 6|...| 79
80|81|82|83|84|85|86|...|159
```

MAC:

```
0| 2| 4| 6| 8|...|71
1| 3| 5| 7| 9|...|143
```

note the sifferent size (Spectre: 512 Byte * 160, MAC: 512 Byte * 144).

micro@imada.dk (Klaus Pedersen) writes:

>Is it possible to use VDI operations to draw on a virtual screen? Possibly
>on a screen which is bigger than the real screen.

Yes, writing on a virtual screen is easy (by setting the logical screen to
your buffer - with 'Setscreen').
But is it possible to change the size of the logical screen?
- Is it possible to tell the VDI about a new size (x,y,planes) ?

I have a nightmare about a user with a video controller with true color at
1024x1024 (thats 3 Mbytes)!!! You need to allocate all 3 Mb before
setting the logical screen!! - can this be true??

Here is another solution to your problem:

In the german magazin "ST-COMPUTER" Nr.11/89 is an article about a completly
new form_do(). With this you can are able to program key selections
(e.g. press O for OK, E for EXIT, etc), corrects several small errors, etc.
Only Problem is, it is written in GFA-BASIC.

From: barry@speaker.metaphor.com
Message-ID: <523@cronos.metaphor.com>
Source record: 48954

When I use the Laser C environment for development, one of the things I've noticed is that programs that run fine under the Laser C shell bomb when I run them from the desktop. My guess is that the Laser shell is catching some traps and handling them internally without letting me know about them.

Anyway, I'm looking for something that gives more useful information than a couple of bombs on the screen. Maybe an ACC that will catch traps and print a stack trace and allow me to dump memory and otherwise poke around a bit so I can figure out what happened.

If this doesn't exist then I could probably write one if I knew how to locate the symbol table and if I knew its format. If anyone has this can they send it to me?

This would help me along greatly while I save up for LaserDB.

Thanks for your help.

1564. GCR + NEC help!

Newsgroup: comp.sys.atari.st.tech
Date: 1991-03-05 19:09:33 UTC
From: kawakami@ocf.berkeley.edu
Message-ID: <1991Mar5.190933.2276@agate.berkeley.edu>
Source record: 48951

I need help getting the mod for the NEC 1037A and 1036 drives to get them to read/write Spectre GCR disks. So far, writes past track $40 (64) or thereabouts are pretty good (only a few problems) on disks formatted on the drive. On disks formatted on a Mac however, reads consistently fail. Same goes for the other direction: Spectre GCR disks are partly unreadable on a real Mac.

I understand there is a fix, and I have not been able to get GBS "live" over the phone, so I'm using the net now.

>Is it safe to even use the blitter during a vbi?

No. Unless you take precautions to make sure that the blitter chip is not
currently in use, you could be interrupting some other blitter operation.

>Does the blitter access memory on video or cpu access times (that is, can
>both the blitter and cpu write to memory at 8 Mhz each (interleaved)?

I don't know that. But don't expect a large speed boost. For straight
memory moves with no shifting or masking operations, the blitter is
almost the same speed as your MOVEM code. I have tried to get it to
go into hog mode, but that seems to interfere with interrupts (such as
mouse interrupts which you don't want to mask) so I can't say how much
faster it is possible to get it to run. Ideally, it takes 128000 clock
cycles to blit 32K of screen RAM, which is only about 20% faster than
what you're getting now.

>And lastly, how do I detect the presence of the blitter?

Xbios function 64 with a parameter of -1. Something like...

```
move.w #$ffff,-(sp)
move.w #$40,-(sp)
trap #14
addq.l #4,sp
```

The return value in D0 tells you. Bits 0 and 1 will tell you whether
the blitter is present and if so, whether it is enabled or not. I don't
remember offhand which bit is which. It's documented in the COMPUTE
and ABACUS books.

For undisclosed reasons, I have canceled Data Innovations license
to distribute Diamond Back II. The following is the text of a public
announcement released to the press concerning the change.

****

Oregon Research Associates is pleased to announce that it will assume
the distribution and support of Diamond Back II effective immediately. The
change in distribution reflects our continuing commitment to the Atari ST
and Diamond Back II owners. "By having direct control over the marketing,
distribution, and support functions I can personally guarantee the
continuation of the high level of product support that Diamond Back II owners
deserve", says Bob Luneski, the President of Oregon Research Associates
and Author of Diamond Back II.

To celebrate this occasion, Oregon Research Associates will release a
major new version of Diamond Back II. The new version includes significant
speed optimization, many new backup and restore options, and an expansion of
the Spectre backup/restore functions. Oregon Research also plans the release
of a comprehensive hard disk optimization and repair program in the second
quarter of 1991.

Current owners of Diamond Back II may obtain the upgrade to V2.20,
which includes a completely rewritten manual, by sending their original
disk and $7.50 to:

1570. Hard Disk Sector 0 Questions

Newsgroup: comp.sys.atari.st.tech
Date: 1991-03-06 16:40:09 UTC
From: ric@mcrware.UUCP
Message-ID: <5208@mcrware.UUCP>
Source record: 48961

Netlanders:

I need to write some software to add partitions to the partition table stored on sector 0 of a hard disk. I will be adding partitions for the areas that are not yet used on the disk. For instance, Joe User has a 80Meg drive and sets up two 30Meg partitions with HDX.PRG. My program wants to then go in there (at the request of the user) and add a partition or two in the unused 20Meg of space. These are not to be GEM partitions, but they should conform as far as the partition table information is concerned.

What I've been able to figure out so far is:

* the partition table starts at 0x1c7
* the table entries are in the following form:

```
struct part_entry {
char name[3];
long start; /* 32-bit sector number */
long length; /* 32-bit length in sectors */
char flag; /* 1 byte flag where 0x01 means bootable */
};
```

* offset 0x1c2 is the start of a 32-bit value for the total number of sectors on the device

My questions are:

1. Is any of the above information inaccurate? Incomplete?

2. What is the significance of the byte at 0x1c6 (sandwiched between the total sectors and the partition table)? On my drive it has the value 0x81 (%10000001).

3. Is there other information in this sector that I will need to write a partitioner?

4. Is there a checksum/parity value kept for sector 0? How does HDX3.01 know it was used to format the hard disk?

5. How might an application read sector 0? All the GEMDOS calls I found dealt with files only, not the whole device.

6. Are there any decent/recent books on this sort of thing?

I suppose that's enough for now.

Thanks in advance for any help that you may be able to provide.

Ric Yeates

From article <bhwhelan.667837119@unix1.tcd.ie>, by bhwhelan@unix1.tcd.ie (Brendan Whelan):
> Does anyone own/know anything about the Hewlett Packard Deskjet
> printer. I'm particularly interested in knowing how it performs
> on an ST.
> Are drivers easily available for it?
> Is there a substitute driver that can be used from most packages with
> it?
> What is it's quality really like?
> How expensive are the cartridges and - most importantly- how often do
> they have to be replaced?
>
> THanks in advance.
>
> B.

I have about 18 mounts on a Deskjet II now. I would not buy it again if
I had it to do over again.

The thing performs as you would expect HP equipmnet to. Well. The
cartridges are about $50 and I have bought 1 new one. Many people heat
a paper clip and burn a couple of small holes in the things and refill
them for the cost of ink. When the printing holes become clogged a new
cartridges is purchased. The Deskjet emulates a couple of other printers,
(I bought an Epson emulation cartridge) and I use the laser jet option
on software that has it. So interfacing it has been no problem.

The thing is SLOW in graphics mode. I mean about 20 minutes/page to print
stuff from Page Stream (a product I think anyone should be wary of). And
this for 300^2 resolution. I must contrast this with an Epson comp 9 pin
printer which I can drive to ~270X240 resolution and dump Page Stream at
about 5 minutes/page. Granted the dot matrix goes thru a lot of ribbons
(which i re-ink), but usually I just can't wait two days for a document to
print out.

In an effort to reduce the print time, I have installed two memory extension
cartridges. There is a noticable improvement in character mode, and no
noticable improvement in graphics mode.

But if;
you primarally want to use the thing in character mode
you place a high value on noise abatement
you can live with a slow printer (with quality at many
laser printer's level)
your pocket book feels the price delta between this
product and a laser printer
this is a good choice

However;
if you will ever want to dump code for review you will
probably want a dot matrix anyway, and a 24 pin Epson
compatible can be driven past 300^2, is cheaper and is
cheaper per copy.

if you need to print a large volume of data in graphics
mode (desk top publishing) stay away from this printer.
You will grow old waiting for page 50.

My opinions are mine, but can be rented for a modest cost. Users
assume all liability.

Message-ID: <1991Mar6.181809.27094@jarvis.csri.toronto.edu>
Source record: 48963

I'm wondering if anyone knows how to get foreign characters to
print out with St-Writer 3.0. At the moment, I'm using a Mega 2
hooked up to a Star NB-24-10 printer (an Epson LQ 24pin clone).
There is the XXYZZ.TXT (or something like this) file and CONFIG.TOS
file sitting around in the St-writer folder (the first is a printer
driver, the other I'm not sure about). Is there any way to
configure ST-writer to properly print foreign characters, or is
the a dip switch or two I have to flip? I've been trying to print
Hungarian characters for months now (including a' e' i' o' u'
o" u"), but I've only been getting funny characters or nothing.

Please contact me email if you run across this problem. Thanks!

1574. 520stfm upgrade?

Newsgroup: comp.sys.atari.st.tech
Date: 1991-03-07 05:10:42 UTC
From: eahsnsr@nmt.edu
Message-ID: <1991Mar7.051042.6372@nmt.edu>
Source record: 48980

I'm really sick of only having 512K and since buying a new computer
is out of the question, I would like to upgrade.

My question is:
OK, I have a Rev. C 520stfm motherboard. In the place where the RAM
chips are, there are a series of empty holes where, I assume, the extra
.5 meg in a 1040 goes. In order to upgrade, could I just simply
solder in the 8(?) memory chips with no other mods, or is there some
trick to it?

Since this thread has probably been beat to death already, and because
our newsfeed has been on the fritz lately, I would appreciate responses
by e-mail.

Thanx.

There is a package called 'mtools' which works for Suns and Ataris.
If anyone knows where I can get it, please let me know. I would be
very grateful.

Thanks in advance!

From: csuab@warwick.ac.uk
Message-ID: <F+D&VM*@warwick.ac.uk>
Source record: 48967

Hi there,

I'd like to here from someone who has got G++ running on there machines. I've had a look at the files on terminator and there appears to be a total lack of README files. I assume that one of the TTP files takes a C++ progam as input and outputs a C program. What I'd like to have running is the gnu C++ translator and Lattice C to do the compilation. Has anyone got a setup like this? What libraries/header files are required? Is it possible?! Most grateful for any help you could give me (I've just been set an assignment in C++, and it would be real useful to have it at home!)

Thanks

Steve

The current version of Mtools and all the patches are available via anonymous
ftp from cerl.cecer.army.mil (129.229.1.101).

1578. Question on Memory/Graphic for 520ST

Newsgroup: comp.sys.atari.st.tech
Date: 1991-03-07 14:11:47 UTC
From: bagdy@dweezl.enet.dec.com
Message-ID: <20852@shlump.nac.dec.com>
Source record: 48966

Question for all those that have had an ATARI-ST for a while.

I just purchased a 520ST with the standard 512K memory and
CGA graphics. I was curious if there were/are any
modifications to upgrade the video/graphics and what the
easiest way to upgrade the memory would be. I'd like to load
this thing with as much memory as physically possible, but
I'm not sure what the limit is for it either.

Any/all help would be greatly appreciated.

Matt Bagdy

Hello there!

I've just gotten hold of a 30 M hard disk and now here is the
trouble. (The type or whatsoever is irrelevant.)

Background: After formatting, the fysical bad sector marking begins
but the program can't find any bad one's even though there
are some fabricial faults on it.

Q: How do I mark them, or more specificaly,
how is the list of bad sectors built. I know where
to find it but not how to use/modify it.

Please email (or why not post?)
any replies to: pa@hexagon.se

AdvTHANKSance!

Whoa!!! $50!?!?!?!?!? Where are you buying your cartridges? I can buy them at Sears Computer Centers for $19.00 and at other local shops for less then that. BTW, HP has come up with a non-water soluble ink so thew printouts don't run it they get wet.

{stuff deleted}

My experience with the Deskjet has been a happy one. I rented Pagestream once to see if it was worth it and had the same speed problem as above. I now stick to GDOS applications and use Migraphs printer driver with OSpooler and the speed is OK. The Deskjet Plus is about five times faster. My church has the Plus and it performs flawlessly.

If I had to do it again I would definitely get a Deskjet Plus.

The SCSI protocol allows one to send a defect list with the Format
command. But I don't know any low-level HD formatting programs for the ST
that allow you to specify the defects, so the program can put them in the SCSI
Format command. Anybody out there know of such a formatting program?

1586. Sozobon C users ... read this

Newsgroup: comp.sys.atari.st.tech
Date: 1991-03-08 14:07:08 UTC
From: L.B.Brown@newcastle.ac.uk
Message-ID: <1991Mar8.140708.27023@newcastle.ac.uk>
Source record: 48978
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

I have just uploaded two files to atari.archive:

newsozo1.zoo,newdlibs.arc

newsozo1.zoo contains the same files as sozobon.zoo (in the languages
directory) but the binaries have been recompiled using a fixed dlibs.a
which, with the source of the fixed .o files, is contained in newdlibs.arc.
(You only need that if you want a complete source for dlibs).

You'll want to know the improvements I suppose:

o All programs compiled under and including the compiler do not crash
when spawned from gemini/mupfel or monitors such as monst.

o The optimizer has been fixed (again!). This time every bit of C source
I have compiles with the -O option, including microemacs 3.10.

o All published mods to dlibs.a have been performed.

More detailed information on the changes can be found in the readme files
in the respective files.

It really is worth uploading this if you use sozobon.

Most of the HD interfaces use the Adaptec Controllers.
4000A for MFM, 4070 for RLL. A 30 meg drive is surely Rll.

The Adaptecs allow a list of bad sectors to be passed to them at format
time. This is the only way to live with spectre and Minix partition.
Tos tries to get by, by "testing" for bad sectors, and mapping them out.
As you see its a poor scheme, at best.

All my drives come with Bad sector lists, and I wrote my own formatter
to utilize this information and format the drive. It has worked well.

The formatter, and associated partitioner is available by EMAIL.

I believe that G++ translates C++ directly to object/assembly code.
You wouldn't need Lattice C then. Also, the header file and libraries
you need are a separate package (forgot the name, but it is explicitly
a GNU C++ library).

It has to be an "oop" partition not the old "ack" one (bill the cat
lives on at gadgets 8-).

I also have problem, and haven't been able to raise gadgets (via the
compuserve gateway). I figure these are trying times for D. Small and
Co., so I'll ask it here. My ancient 520 has a mouse and keyboard
problem under Spectre - the machine just loses the mouse unpredicably
(no response on the screen) after a while, and of course, the keyboard
is dead too. I have the GCR box and 2 more Megs of memory plugged in,
so I figure the voltage to the keyboard could be low (haven't checked
yet) or I could have a flakey IKBD processor. Anybody have any other
guesses, possible fixes and/or experiences to relate? I don't want to
buy a new keyboard processor only to find that my problem is elsewhere.

If I have to replace my dinky external power supply (PS or PSU for the
abbreviation inclined 8-), what's best? I have just gotten a new
shoebox w/power for the disk drive, so don't suggest a PC case 8-).
On the other hand, info on U.S. legal and well designed replacement
cases (available in the U.S.A.) would be interesting. Remember, I *do
not have an STFM* the power supply is external.

The easiest way to use a partially bad HD is to just mark the bad sectors
in the FAT as used (FFF7 or something) so they will never be allocated
again. Of course an optimizer might find them as lost clusters again...

Well, I don't know how to do this using your printer's character set, but I have a product (shameless plug warning) called G-Print which prints out ST Writer files (as well as 1st Word Plus and Word Writer) files using GDOS fonts which makes the whole character set accessible. It has a number of other features (including multiple fonts) upon which I will gladly elaborate if asked. For more information, send me mail. It sells for US$25.

My disk drive has numbers like "cylinder head bytes-from-index" in the defect list that accompanied it. How do I turn these into FAT indices? I don't want to rely on high-level read\write tests to discover them, because the manufacturer applied stricter tests than one can do with ordinary I/O. I'd rather not write data where the manufacturer thinks his product is marginal, only to have it disappear without warning (that is, between being written and the first subsequent backup).

From: dgjst@unix.cis.pitt.edu
Message-ID: <101430@unix.cis.pitt.edu>
Source record: 48983

Hello, my mono mon. went bad a little while ago, and if
anyone recognizes the problem and knows a fix I'd appreciate
hearing from them.

SYMPTOMS: the image shifted to the left hand side of the screen
very bright line through the center of what image is left
image is the wrong term--VERY distorted view of the
desktop with parts of a few icons visible.

This problem occured suddenly, with no prior symptoms. It has
been in daily use for over a year.

If this sounds familiar, how do you fix it or
how much did you pay to have it fixed.

Thanks in advance,
Dan Jones

The manual said that you just had to select "erase disk" from Finder to
change an ACK partition to an OOP partition. I did that. I guess we'll
wait until dsmall gets caught up a bit before hitting him with this
question.

If you have ICD software, then you will find the program called HDUTIL, under it there is a function called Map Bad disk setors. This will allow you to mark a sector to be bad in the FAT. And also if you used Adaptec 4070 controller, the bad sectors are map out by the card when it format the disk (that's what I remember but not 100% certain, but do seems to recall some SCSI card map out the bad sectors so that the host sees the hard drive as no bad sectors).

There is a Pot, VR 701 Horiz Centering, this is on the main PCB,
near the front, on the right side, this could need ajusting.

!!! WARNING !!! this is close to the EHT circuits, and that is a
Voltage of 10,000 Volts, so use a long plastic trimmer (10")
and please take precourtions...

IE. ajust Pot, with power off..

Hi !!

A little more info would help: have you tried any other mono or color monitors?

From your brief description, it sound like your video shifter chip went bezerk. A very simple attempt at a fix would be to carefully pop out the shifter chip and reseat it. I have seen many a device come to life after this simple procedure. Reseating a chip merely scrapes off some oxidation form its pins. If you need help locating and removing the video shifter chip, post another message.

If a reseat doesn't do it, fret not. A video shifter chip can be purchased for about $40 from somewhere.

I've got software that lets me mark FAT entries to indicate bad clusters, and software that tries to discover which sectors are bad. But the disk manufacturer uses a more stringent test than one can do with I/O through the SCSI. I have an Adaptec 4000, and manual. It's DEFINITELY possible to tell the controller about the bad spots. The problem is, none of the *low-level* formatting programs I've tried know how to tell the controller about the manufacturer's defect list. I'd much prefer to tell the Adaptec where the bad spots are in advance, than discover there's a bad spot in something I've just spent 20 hours creating. (I do backups, but not continuously). It's the *low-level* formatting program that's got to tell the Adaptec where the manufacturer says the bad spots are. Unless somebody can provide a fool-proof (i.e. works with EVERYBODY's HD SW) algorithm for converting the "cylinder/head/bytes-from-index" indication of bad spots into partition/cluster-number indication. BTW, marking FATs won't work the same way on Magic, GCR, Minix, etc. partitions, so telling the Adaptec seems the only reliable way.

1603. mono monitor problem (UPDATE)

Newsgroup: comp.sys.atari.st.tech
Date: 1991-03-11 01:03:15 UTC
From: dgjst@unix.cis.pitt.edu
Message-ID: <101833@unix.cis.pitt.edu>
Source record: 48791

Hello,
Thanks for the response so far.
I'm reasonably convinced that the problem is
in the monitor itself, I have 2 STs and I tried the
monitor on both with the symptoms occuring on both.
Also, my sc1224 color mon works fine with
both. Unless its something affecting only mono,
and it's broken in both boxes, the problem is with
the monitor.

Thanks, I really appreciate the help.

I know the follow probably is one of the Frequently Asked Questions but
I really need this info:

I'd like to connect a second Floppy Drive on my 1040STf.
Are the ST drives the same on the PC (Ibm/Clone)?
If yes how can I connect it?
If no, what's the difference? Is there a way to go around ?
Do you have a list of the working Drive (manufacturer, Type, etc.)?

And now the 1 Billion dollars question:

It is possible to connect as 2nd drive a 1.44MB one???
HOW?

Thank you ST friends.

Savino

I've been working on something like this, but I ended up concluding that
the Adaptec 4000 has firmware bugs in it that make it impossible to transfer\
a defect list when formatting. Recently, I received indications that there
might be a way to do it, but I have no details on that. Somebody out there
who can tell us the tricks?

> are some fabricial faults on it.

If it is a true SCSI drive (as opposed to MFM or RLL w/Adaptec controller)
you don't need to worry about defects - SCSI is known as "perfect media",
where there are spare sectors on the disk, and any bad sector is automatically
remapped to one of the spare sectors. The computer has no way of knowing
this is taking place - the firmware on the drive does it. To the computer,
there are no bad sectors.

Again, this is only true for an embedded-SCSI drive.

1607. Mouse and Keyboard dieing - fixes?

Newsgroup: comp.sys.atari.st.tech
Date: 1991-03-11 19:06:33 UTC
From: pegram@kira.UUCP
Message-ID: <1991Mar11.190633.9121@uvm.edu>
Source record: 48797
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

In reply to another question to do with Spectre, I wrote about my
mouse and keyboard dieing (no response all of a sudden) under Spectre.
I speculated that my external floppy 520's power was being overloaded
or that the IKBD processor was going.

Last night, I substituted a later (beefier?) Atari switching Power
supply (PS) for my original non-switching supply. Result: the mouse
is now dieing under TOS. I guess that's progress - I was pretty sure
that the problem was not Dave Small's code. However, has anyone else
had this problem - must I replace the IKBD processor, or just clean
and reseat it? For that matter, could this problem be due to something
I'm not considering? After all, both processors *and* their software *and*
the cabling between them must be in good shape, right? I have rather
beaten on the cable to the motherboard in past times 8-).

Thanks for any help,
Bob Pegram

I have an older (purchased in 1986) ST with tos 1.0. It has an easieST memory expansion board installed with 2mb for a total of 2.5 mb of memory. Recently, when the machine is warm -- on for at least 1 1/2 hours -- it locks up. Narrow vertical lines appear on the screen as do eleven bombs. If I can successfully reboot I often get a machine with only 1/2 mb of memory available. I had the connections to expansion board soldered in. That has improved but not completely solved the problem; the same thing happens, but less often and the computer can be on longer before it happens. Any ideas? Anybody else ever have some thing like this happen to them? Much thanks in advance!!!

Try to insert a gold-plated sockes between the original sockes and the
keyboard processor.

Atari uses lousy sockets...

We're working on the next official release of Sozobon C and hope
to release it in the near future. We really appreciate all the work
that people like Leigh have put into the compiler. We don't have
access to all the hardware/software combinations that people are
using, so fixes like these are a tremendous help.

We'd like to incorporate all the fixes and improvements that people
have made, as well as some of our own (long identifiers, for one).
If you've made bug fixes or added features, please send them to me
via email or disk. We've had trouble reaching some of the archive
servers, so please send us your fixes even if they are available
on a server somewhere.

If you send your changes by disk, send it to:

Tony Andrews
4704 Berkshire Ct.
Boulder, CO 80301
USA

I can't promise a response to each message, but we'll do our best to
incorporate your changes in the release. Thanks again for your work!

In article <1991Mar6.182031.11905@unislc.uucp>, dgb@unislc.uucp (Douglas Barrett) says:
>
>The thing is SLOW in graphics mode. I mean about 20 minutes/page to print
>stuff from Page Stream (a product I think anyone should be wary of). And

[more stuff deleted]

I can't agree with Douglas opinion. I'm using a DeskJet 500 (the newest DeskJet version) and it is FAST. In normal text mode the speed is the same as good dot-matrix printers like the NEC P6+. The graphic mode is much faster than a dot-matrix printer. I have a german TeX with a DeskJet driver. A page with a resolution of 300 DPI will be printed in one minute. The speed will behaive on the quality of the driver (will it use system-calls or will it program the I/O hardware direct, will the compressed mode for the graphics data be used). Programs that need more time to print will need 2 or 3 minutes. I think Douglas problem will be a result of an older printer version and a BAD driver.

> struct part_entry {

WRONG !!! flag has to be here, bit 7 means bootable

> char name[3];
> long start; /* 32-bit sector number */
> long length; /* 32-bit length in sectors */
> char flag; /* 1 byte flag where 0x01 means bootable */
> };
> 1. Is any of the above information inaccurate? Incomplete?

Yes. :-)

More questions answered below.

> 5. How might an application read sector 0? All the GEMDOS calls I found
> dealt with files only, not the whole device.

If you detect an AHDI or compatible driver, you can set bit 3 in the
Rwabs() mode-word to read physical sectors, but to be safe you will
have to use direct DMA access. (Ask your Microware devdrvr writers)

In germany, there's a VERY good book, called 'Scheibenkleister',
published by Maxon. It's about all mass-storage devices on the ST.
I don't think that there is an english version, so you'll have to
search somebody reading ger-mish - it worth the action.

I include the C definitions I use for such tools:
(ICD/Supra Rootsectors only - there are official docs from Atari
describing HDX 3.0 Format, but they are (c), so you have to ask Atari.

Hope that helps, Bjoern

```
#define PART_EXIST 1
#define PART_BOOT 128

/* partition definition */

Can a DA have a menu bar?

I have a program that, when run as a PRG, paints and responds to its menu bar just fine. When run as an ACC, the next meaningful action after MenuBar(...) is reaching for the reset button. If I take out the MenuBar(), the rest of the ACC works fine.

Is this a GEM restriction, or am I just not holding my mouth right?

Thanks in advance.

1618. Upgrading an Atari SS drive to DS

Newsgroup: comp.sys.atari.st.tech
Date: 1991-03-12 23:58:21 UTC
From: ldl2142@galileo.rtn.ca.boeing.com
Message-ID: <324@galileo.rtn.ca.boeing.com>
Source record: 48803

I believe that this has been discussed previously, but could someone out there please post some clear, complete directions on what is required to upgrade an Atari Single Sided Floppy disk to a DS disk?

I'm interested in which types of drive mechanisms can be used (If there are any restrictions, that is.), as well as what switches, wires, etc. must be modified for the drive to be recognized as DS.

As an aside, does anyone know if any drive mechanisms other than the NEC have problems with the Spectre GCR?

If someone has this info, but doesn't want to post it, please email me at

ldl2142@galileo.rtn.ca.boeing.com

Thanks,

Layne Lommen

1619. Monochrome Monitor Problem

Newsgroup: comp.sys.atari.st.tech
Date: 1991-03-13 03:27:45 UTC
From: os9paul@gkcl.ists.ca
Message-ID: <20101@ists.ists.ca>
Source record: 48806
Cross-posted to: comp.sys.atari.st.tech,comp.sys.atari.st

I recently purchased a 'previously owned' SM124 monochrome monitor. It seems to work quite nicely except for one minor problem. When the display is a black background and there is very little text on the screen, the image is quite dim. As more characters are displayed the image brightens as if the brightness control were being turned up.

Any comments or suggestions about possible components to check/replace? The monitor is from Korea and is dated December 1987.

Hi.. I have two problems that I hope I can get some help with..
I have an older Monochrome monitor Feb 1987. It has this nice problem...
it likes to invert everything.... For example I turn it on and all I get is
a solid black screwwn after I "SMACK" it on its side I get the normal black
text on the white screen.. then a few minutes later it flashes black and then
white then black again, and then I have a black background with white lettering
???!!! If I smack the monitor a few times it will usually go back to normal use
it likes to flicker and change alot.... Any ideas <DONT SAY ITS A LOOSE
CONNECTION!!>??!!!

ALSO

Does anyone know if GREEK lettering fonts either GDOS or not are available
for the ST.. Otherwise How could I create my own font???!

Jeremy

>Can a DA have a menu bar?

Unfortunately, it cannot. A GEM restriction.

> ST? Preferably also one that includes a library aware of AES and VDI.

XLISP is getting closer and closer to Common LISP, although it is nowhere
near Steele's specifications yet (if you have used pre-2.0 versions, look
again!). I used XLISP a lot at v. 1.7, and it was easy to add VDI/AES
to it (just build in low-level functions to access the GEM arrays, etc.,
then build up the interface in LISP); this is presuming that you have
a C compiler, of course.

Another option would be to use it under MGR (where it runs beautifully),
and write the MGR graphic interface entirely in LISP. MGR uses escape
sequences for all of its graphic work, so you would not have to
change or recompile XLISP itself.

I wouldn't flame you unless you wanted to use InterLISP.

In article <12052@hydra.Helsinki.FI>, luoto@cs.Helsinki.FI (Markku Luoto) says:
>
>I opened it once and the drive was a seagate... but how can you tell wether
>it's a mfm or something else ???
>

Hello Markku!

If the drive was a Seagate it is very easy: Look at the drive type on the cover
If the last character was a digit, it was a MFM drive (e.g. ST 225, 20 MB
5 1/4 inch MFM drive). If the last character was a R, it was an RLL drive
(e.g. ST 238R, 5 1/4 inch 30 MB RLL drive).
I hope this will help you.

1624. SM124 Monochrome monitor problem (an another one).

Newsgroup: comp.sys.atari.st.tech
Date: 1991-03-13 13:22:43 UTC
From: geert@ahds.UUCP
Message-ID: <1483@ahds.UUCP>
Source record: 48811
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

It occurred to me that many other SM124 owners seems to have problems
with their monitor (looking at the news).

Well, here's my problem.

When ca. 3/4 of the screen is black, i rarely can't read the 1/4 that's
white and still on the screen.
You know that that will disturb me (especially when I use
Minix, which uses a black background, or using programs that are
inverting the screen).

Has anyone has the same problem, and can it be fixed????
Please help !!!!!!!! Help will be appreciated.

Thanks in advance!

Geert.

1625. Bad.sector.list again. (Clarifications etc.)

Newsgroup: comp.sys.atari.st.tech
Date: 1991-03-13 13:31:56 UTC
From: pa@hexagon.se
Message-ID: <3028@hexagon.se>
Source record: 48817

First I must thank all these people helping me in this matter.
It seems that I drew some issue from the bottom of every hard disk
owner's mind with my humble question about the bad sector format...
But... I didn't reach any further about the actual format of these
sectors. What I really wanted was a little hint about what to do to find
these bad sectors (actually, they aren't hard to find, I have already
spotted one or two just by putting things in them) and how to mark them.

A solution to this problem of mine is to read (and then write) to each
and every sector, spot the bad ones (via BIOS's rwabs function) and then
mark them. Perhaps one need to check every sector one or two times
but that is not a problem.

HOW to mark them is still a mystery to me... Well, not really.
I just need the format of the bad.list.

While I'm on the go: Please send me your formatterprograms (that are PD)
and any other utility that might be useful (such as backupprogs and such).
I'd be very grateful.

Thank you all, again.

Peter Andersson.
